Chapter 1

Introduction

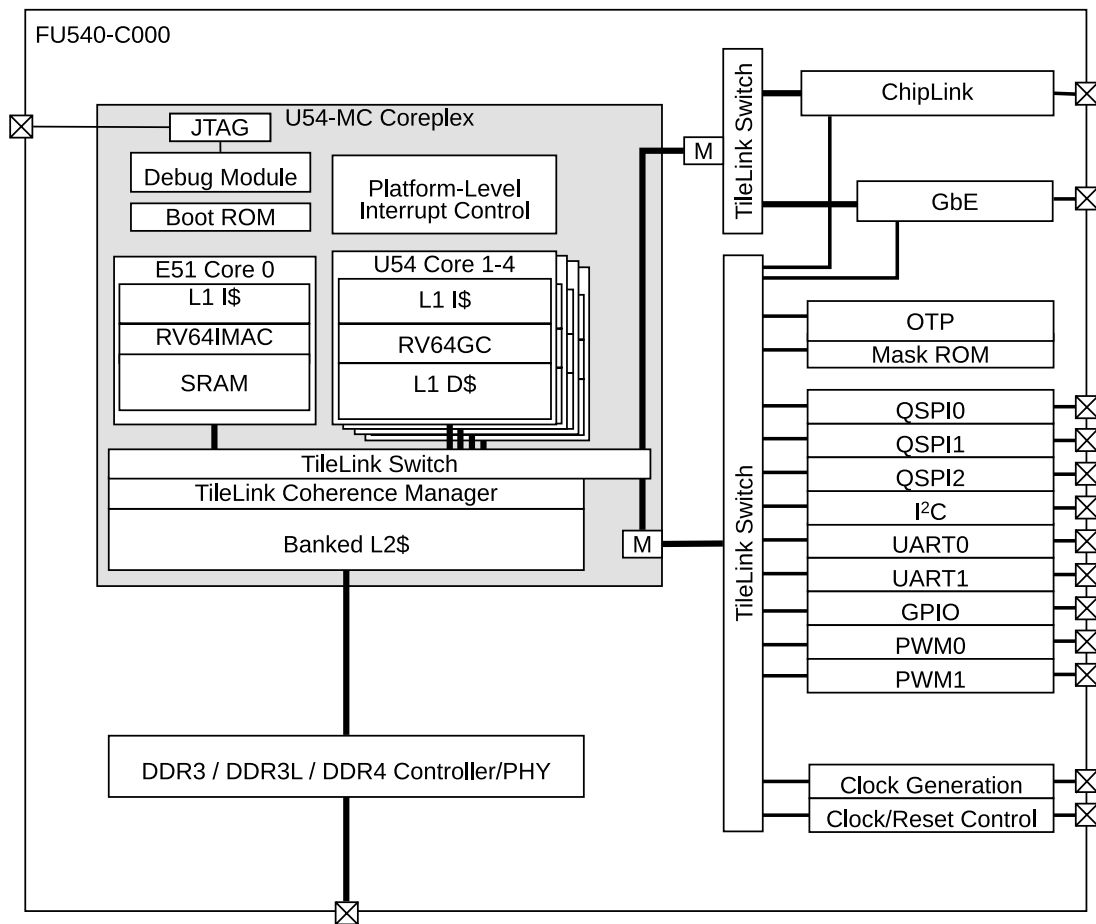

The FU540-C000 is the world's first 4+1 64-bit RISC-V SoC, capable of supporting full-featured operating systems, such as Linux. It is the basis for the HiFive Unleashed Development Platform for the Freedom U500 family. The FU540-C000 is built around the U54-MC Core Complex instantiated in the Freedom U500 platform and fabricated on TSMC 28HPC 28 nm process. This manual describes the specific configuration for the FU540-C000.

The FU540-C000 is compatible with all applicable RISC-V standards, and this document should be read together with the official RISC-V user-level, privileged, and external debug architecture specifications.

1.1 FU540-C000 Overview

Figure 1 shows the overall block diagram of the FU540-C000, which contains a U54-MC Core Complex with a 2 MiB coherent L2 cache, 64-bit + ECC DDR3/4 controller, 3 QSPI controllers, 2 UARTs, I²C, 2 PWMs, Gigabit Ethernet MAC, and ChipLink for connecting to external ChipLink peripherals.

A feature summary table can be found in Table 1.

**Figure 1:** FU540-C000 top-level block diagram.

Feature	Description
RISC-V Core	4× U54 RISC-V cores with machine, supervisor, and user mode, 32 KiB 8-way L1 I-cache, and 32 KiB 8-way L1 D-cache. 4× E51 RISC-V cores with machine and user mode, 16 KiB 2-way L1 I-cache, and 8 KiB data tightly integrated memory (DTIM).
L2 Cache	2 MiB 16-way coherent L2 cache.
Interrupts	Software and timer interrupts, 53 peripheral interrupts connected to the PLIC with 7 levels of priority.
DDR3/4 Controller	64 bit + ECC Memory Controller to external DDR3/DDR3L/DDR4 memory
UART 0	Universal Asynchronous/Synchronous Transmitters for serial communication.
UART 1	Universal Asynchronous/Synchronous Transmitters for serial communication.
QSPI 0	Serial Peripheral Interface. QSPI 0 has 1 chip select signal.
QSPI 1	Serial Peripheral Interface. QSPI 1 has 4 chip select signals.
QSPI 2	Serial Peripheral Interface. QSPI 2 has 1 chip select signal.
PWM 0	16-bit Pulse-width modulator with 4 comparators.
PWM 1	16-bit Pulse-width modulator with 4 comparators.
I ² C 0	Inter-Integrated Circuit (I ² C) controller.
GPIO	16 General Purpose I/O pins.
Gigabit Ethernet MAC	10/100/1000 Ethernet MAC with GMII interface to an external PHY.
OTP	4Kx32b one-time programmable memory.

Table 1: FU540-C000 Feature Summary.

1.2 E51 RISC-V Monitor Core

The FU540-C000 includes a 64-bit E51 RISC-V core, which has a high-performance single-issue in-order execution pipeline, with a peak sustainable execution rate of one instruction per clock cycle. The E51 core supports Machine and User privilege modes as well as standard Multiply, Atomic, and Compressed RISC-V extensions (RV64IMAC).

The monitor core is described in more detail in Chapter 3.

1.3 U54 RISC-V Application Cores

The FU540-C000 includes four 64-bit U54 RISC-V cores, which each have a high-performance single-issue in-order execution pipeline, with a peak sustainable execution rate of one instruction per clock cycle. The U54 core supports Machine, Supervisor, and User privilege modes as well as standard Multiply, Single-Precision Floating Point, Double-Precision Floating Point, Atomic, and Compressed RISC-V extensions (RV64IMAFDC).

The application cores are described in more detail in Chapter 4.

1.4 Interrupts

The FU540-C000 includes a RISC-V standard platform-level interrupt controller (PLIC), which supports 53 global interrupts with 7 priority levels. The FU540-C000 also provides the standard RISC-V machine-mode timer and software interrupts via the Core Local Interruptor (CLINT).

Interrupts are described in Chapter 8. The CLINT is described in Chapter 9. The PLIC is described in Chapter 10.

1.5 On-Chip Memory System

Each U54 core's private L1 instruction and data caches are configured to be a(n) 8-way set-associative 32 KiB cache. The E51 monitor core has a(n) 2-way set-associative 16 KiB L1 instruction cache.

The shared 2 MiB L2 cache is divided into 4 address-interleaved banks to improve performance. Each bank is 512 KiB and is a(n) 16-way set-associative cache. The L2 also supports runtime reconfiguration between cache and scratchpad RAM uses. The L2 cache acts as the system coherence hub, with an inclusive directory-based coherence scheme to avoid wasting bandwidth on snoops.

All on-chip memory structures are protected with parity and/or ECC, and all cores have Physical Memory Protection (PMP) units.

The Level 1 memories are described in Chapter 3 and Chapter 4, the PMP is described in Section 3.7 and Section 4.9, and the L2 Cache Controller is described in Chapter 11.

1.6 Universal Asynchronous Receiver/Transmitter

Multiple universal asynchronous receiver/transmitter (UARTs) are available and provide a means for serial communication between the FU540-C000 and off-chip devices.

The UART peripherals are described in Chapter 13.

1.7 Pulse Width Modulation

The pulse width modulation (PWM) peripheral can generate multiple types of waveforms on GPIO output pins and can also be used to generate several forms of internal timer interrupt.

The PWM peripherals are described in Chapter 14.

1.8 I²C

The FU540-C000 has an I²C controller to communicate with external I²C devices, such as sensors, ADCs, etc.

The I²C is described in detail Chapter 15.

1.9 Hardware Serial Peripheral Interface (SPI)

There are 3 serial peripheral interface (SPI) controllers. Each controller provides a means for serial communication between FU540-C000 and off-chip devices, like quad-SPI Flash memory. Each controller supports master-only operation over single-lane, dual-lane, and quad-lane protocols. Each controller supports burst reads of 32 bytes over TileLink to accelerate instruction cache refills. 2 SPI controllers can be programmed to support eXecute-In-Place (XIP) modes to reduce SPI command overhead on instruction cache refills.

The SPI interface is described in more detail in Chapter 16.

1.10 GPIO Peripheral

The GPIO Peripheral manages the connections to low-speed pads for generic I/O operations. GPIO control includes pin direction, setting and getting pin values, configuring interrupts, and controlling dynamic pull-ups.

The GPIO complex is described in more detail in Chapter 17.

1.11 Gigabit Ethernet MAC

The FU540-C000 has a Gigabit (10/100/1000) Ethernet MAC as defined in IEEE Standard for Ethernet (IEEE Std. 802.3-2008). The Gigabit Ethernet MAC interfaces to an external PHY using Gigabit Media Independent Interface (GMII).

The Gigabit Ethernet MAC is described in detail in Chapter 19.

1.12 DDR Memory Subsystem

The FU540-C000 has a DDR subsystem that supports an external 64-bit wide DDR3, DDR3L or DDR4 DRAM with optional ECC at a maximum data rate of 2400 MT/s.

Chapter 20 describes the details of the DDR Memory Subsystem.

1.13 Debug Support

The FU540-C000 provides external debugger support over an industry-standard JTAG port, including 2 hardware-programmable breakpoints per hart.

Debug support is described in detail in Chapter 23, and the debug interface is described in Chapter 24.

Chapter 2

List of Abbreviations and Terms

Term	Definition
BHT	Branch History Table
BTB	Branch Target Buffer
RAS	Return-Address Stack
CLINT	Core Local Interruptor. Generates per-hart software interrupts and timer interrupts.
hart	HARdware Thread
DTIM	Data Tightly Integrated Memory
ITIM	Instruction Tightly Integrated Memory
JTAG	Joint Test Action Group
LIM	Loosely Integrated Memory. Used to describe memory space delivered in a SiFive Core Complex but not tightly integrated to a CPU core.
PMP	Physical Memory Protection
PLIC	Platform-Level Interrupt Controller. The global interrupt controller in a RISC-V system.
TileLink	A free and open interconnect standard originally developed at UC Berkeley.
RO	Used to describe a Read Only register field.
RW	Used to describe a Read/Write register field.
WO	Used to describe a Write Only registers field.
WARL	Write-Any Read-Legal field. A register field that can be written with any value, but returns only supported values when read.
WIRI	Writes-Ignored, Reads-Ignore field. A read-only register field reserved for future use. Writes to the field are ignored, and reads should ignore the value returned.
WLRL	Write-Legal, Read-Legal field. A register field that should only be written with legal values and that only returns legal value if last written with a legal value.
WPRI	Writes-Preserve Reads-Ignore field. A register field that might contain unknown information. Reads should ignore the value returned, but writes to the whole register should preserve the original value.

Chapter 3

E51 RISC-V Core

This chapter describes the 64-bit E51 RISC-V processor core used in the FU540-C000. The E51 processor core comprises an instruction memory system, an instruction fetch unit, an execution pipeline, a data memory system, and support for global, software, and timer interrupts.

The E51 feature set is summarized in Table 2.

Feature	Description
ISA	RV64IMAC.
Instruction Cache	16 KiB 2-way instruction cache.
Instruction Tightly Integrated Memory	The E51 has support for an ITIM with a maximum size of 8 KiB.
Data Tightly Integrated Memory	8 KiB DTIM.
ECC Support	Single error correction, double error detection on the ITIM and DTIM.
Modes	The E51 supports the following modes: Machine Mode, User Mode.

Table 2: E51 Feature Set

3.1 Instruction Memory System

The instruction memory system consists of a dedicated 16 KiB 2-way set-associative instruction cache. The access latency of all blocks in the instruction memory system is one clock cycle. The instruction cache is not kept coherent with the rest of the platform memory system. Writes to instruction memory must be synchronized with the instruction fetch stream by executing a FENCE.I instruction.

The instruction cache has a line size of 64 bytes, and a cache line fill triggers a burst access. The core caches instructions from executable addresses, with the exception of the Instruction Tightly Integrated Memory (ITIM), which is further described in Section 3.1.1. See the FU540-C000 Memory Map in Chapter 5 for a description of executable address regions that are denoted by the attribute X.

Trying to execute an instruction from a non-executable address results in a synchronous trap.

3.1.1 I-Cache Reconfigurability

The instruction cache can be partially reconfigured into ITIM, which occupies a fixed address range in the memory map. ITIM provides high-performance, predictable instruction delivery. Fetching an instruction from ITIM is as fast as an instruction-cache hit, with no possibility of a cache miss. ITIM can hold data as well as instructions, though loads and stores from a core to its ITIM are not as performant as loads and stores to its Data Tightly Integrated Memory (DTIM). Memory requests from one core to any other core's ITIM are not as performant as memory requests from a core to its own ITIM.

The instruction cache can be configured as ITIM for all ways except for 1 in units of cache lines (64 bytes). A single instruction cache way must remain an instruction cache. ITIM is allocated simply by storing to it. A store to the n^{th} byte of the ITIM memory map reallocates the first $n+1$ bytes of instruction cache as ITIM, rounded up to the next cache line.

ITIM is deallocated by storing zero to the first byte after the ITIM region, that is, 8 KiB after the base address of ITIM as indicated in the Memory Map in Chapter 5. The deallocated ITIM space is automatically returned to the instruction cache.

For determinism, software must clear the contents of ITIM after allocating it. It is unpredictable whether ITIM contents are preserved between deallocation and allocation.

3.2 Instruction Fetch Unit

The E51 instruction fetch unit contains branch prediction hardware to improve performance of the processor core. The branch predictor comprises a 30-entry branch target buffer (BTB) which predicts the target of taken branches, a 256-entry branch history table (BHT), which predicts the direction of conditional branches, and a 6-entry return-address stack (RAS) which predicts the target of procedure returns. The branch predictor has a one-cycle latency, so that correctly predicted control-flow instructions result in no penalty. Mispredicted control-flow instructions incur a three-cycle penalty.

The E51 implements the standard Compressed (C) extension to the RISC-V architecture, which allows for 16-bit RISC-V instructions.

3.3 Execution Pipeline

The E51 execution unit is a single-issue, in-order pipeline. The pipeline comprises five stages: instruction fetch, instruction decode and register fetch, execute, data memory access, and register writeback.

The pipeline has a peak execution rate of one instruction per clock cycle, and is fully bypassed so that most instructions have a one-cycle result latency. There are several exceptions:

- LW has a two-cycle result latency, assuming a cache hit.
- LH, LHU, LB, and LBU have a three-cycle result latency, assuming a cache hit.
- CSR reads have a three-cycle result latency.
- MUL, MULH, MULHU, and MULHSU have a 5-cycle result latency.
- DIV, DIVU, REM, and REMU have between a 2-cycle and 65-cycle result latency, depending on the operand values.

The pipeline only interlocks on read-after-write and write-after-write hazards, so instructions may be scheduled to avoid stalls.

The E51 implements the standard Multiply (M) extension to the RISC-V architecture for integer multiplication and division. The E51 has a 16-bit per cycle hardware multiply and a 1-bit per cycle hardware divide.

Branch and jump instructions transfer control from the memory access pipeline stage. Correctly-predicted branches and jumps incur no penalty, whereas mispredicted branches and jumps incur a three-cycle penalty.

Most CSR writes result in a pipeline flush with a five-cycle penalty.

3.4 Data Memory System

The E51 data memory system consists of a DTIM. The access latency from a core to its own DTIM is two clock cycles for full words and three clock cycles for smaller quantities. Memory requests from one core to any other core's DTIM are not as performant as memory requests from a core to its own DTIM. Misaligned accesses are not supported in hardware and result in a trap to allow software emulation.

Stores are pipelined and commit on cycles where the data memory system is otherwise idle. Loads to addresses currently in the store pipeline result in a five-cycle penalty.

3.5 Atomic Memory Operations

The E51 core supports the RISC-V standard Atomic (A) extension on the DTIM and the peripheral memory region. Atomic memory operations to regions that do not support them generate an access exception precisely at the core.

The load-reserved and store-conditional instructions are only supported on cached regions, hence generate an access exception on DTIM and other uncached memory regions.

See *The RISC-V Instruction Set Manual, Volume I: User-Level ISA, Version 2.1* for more information on the instructions added by this extension.

3.6 Supported Modes

The E51 supports RISC-V user mode, providing two levels of privilege: machine (M) and user (U).

U-mode provides a mechanism to isolate application processes from each other and from trusted code running in M-mode.

See *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10* for more information on the privilege modes.

3.7 Physical Memory Protection (PMP)

The E51 includes a Physical Memory Protection (PMP) unit compliant with *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*. PMP can be used to set memory access privileges (read, write, execute) for specified memory regions. The E51 PMP supports 8 regions with a minimum region size of 4 bytes.

This section describes how PMP concepts in the RISC-V architecture apply to the E51. The definitive resource for information about the RISC-V PMP is *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*.

3.7.1 Functional Description

The E51 includes a PMP unit, which can be used to restrict access to memory and isolate processes from each other.

The E51 PMP unit has 8 regions and a minimum granularity of 4 bytes. Overlapping regions are permitted. The E51 PMP unit implements the architecturally defined `pmpcfgX` CSR `pmpcfg0` supporting 8 regions. `pmpcfg1`, `pmpcfg2`, and `pmpcfg3` are implemented but hardwired to zero.

The PMP registers may only be programmed in M-mode. Ordinarily, the PMP unit enforces permissions on U-mode accesses. However, locked regions (see Section 3.7.2) additionally enforce their permissions on M-mode.

3.7.2 Region Locking

The PMP allows for region locking whereby, once a region is locked, further writes to the configuration and address registers are ignored. Locked PMP entries may only be unlocked with a system reset. A region may be locked by setting the L bit in the `pmpicfg` register.

In addition to locking the PMP entry, the L bit indicates whether the R/W/X permissions are enforced on M-Mode accesses. When the L bit is set, these permissions are enforced for all privilege modes. When the L bit is clear, the R/W/X permissions apply only to U-mode.

3.8 Hardware Performance Monitor

The FU540-C000 supports a basic hardware performance monitoring facility compliant with *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*. The `mcycle` CSR holds a count of the number of clock cycles the hart has executed since some arbitrary time in the past. The `minstret` CSR holds a count of the number of instructions the hart has retired since some arbitrary time in the past. Both are 64-bit counters.

The hardware performance monitor includes two additional event counters, `mhpmcounter3` and `mhpmcounter4`. The event selector CSRs `mhpmevent3` and `mhpmevent4` are registers that control which event causes the corresponding counter to increment. The `mhpmcounters` are 40-bit counters.

The event selectors are partitioned into two fields, as shown in Table 3: the lower 8 bits select an event class, and the upper bits form a mask of events in that class. The counter increments if the event corresponding to any set mask bit occurs. For example, if `mhpmevent3` is set to `0x4200`, then `mhpmcounter3` will increment when either a load instruction or a conditional branch instruction retires. Note that an event selector of 0 means "count nothing."

Machine Hardware Performance Monitor Event Register	
Instruction Commit Events, mhpeventX[7:0] = 0	
Bits	Meaning
8	Exception taken
9	Integer load instruction retired
10	Integer store instruction retired
11	Atomic memory operation retired
12	System instruction retired
13	Integer arithmetic instruction retired
14	Conditional branch retired

17	Integer multiplication interlock
Memory System Events, mhpeventX[7:0] = 2	
Bits	Meaning
8	Instruction cache miss
9	Memory-mapped I/O access

Table 3: mhpevent Register Description

3.9 ECC

The E51 Instruction Cache and ITIM implement Single-Error Correcting and Double-Error Detecting (SECCDED) Error Correcting Code. The granularity at which this protection is applied (the codeword) is 32-bit (with an ECC overhead of 7 bits per codeword).

3.9.1 Single Bit Errors

In the case of a single-bit error in the L1 Instruction Cache, the error is corrected, and the cache line is flushed. When a single-bit error is detected in the ITIM or the DTIM, the error is corrected and written back to the SRAM.

Chapter 4

U54 RISC-V Core

This chapter describes the 64-bit U54 RISC-V processor core used in the FU540-C000. The U54 processor core comprises an instruction memory system, an instruction fetch unit, an execution pipeline, a floating-point unit, a data memory system, a memory management unit, and support for global, software, and timer interrupts.

The U54 feature set is summarized in Table 4.

Feature	Description
ISA	RV64IMAFDC.
Instruction Cache	32 KiB 8-way instruction cache.
Instruction Tightly Integrated Memory	The U54 has support for an ITIM with a maximum size of 28 KiB.
Data Cache	32 KiB 8-way data cache.
ECC Support	Single error correction, double error detection on the ITIM and Data Cache.
Virtual Memory Support	The U54 has support for Sv39 virtual memory support with a 39-bit virtual address space, 38-bit physical address space, and a 32-entry TLB.
Modes	The U54 supports the following modes: Machine Mode, Supervisor Mode, User Mode.

Table 4: U54 Feature Set

4.1 Instruction Memory System

The instruction memory system consists of a dedicated 32 KiB 8-way set-associative instruction cache. The access latency of all blocks in the instruction memory system is one clock cycle. The instruction cache is not kept coherent with the rest of the platform memory system. Writes to instruction memory must be synchronized with the instruction fetch stream by executing a FENCE.I instruction.

The instruction cache has a line size of 64 bytes, and a cache line fill triggers a burst access. The core caches instructions from executable addresses, with the exception of the Instruction Tightly Integrated Memory (ITIM), which is further described in Section 3.1.1. See the FU540-C000 Memory Map in Chapter 5 for a description of executable address regions that are denoted by the attribute X.

Trying to execute an instruction from a non-executable address results in a synchronous trap.

4.1.1 I-Cache Reconfigurability

The instruction cache can be partially reconfigured into ITIM, which occupies a fixed address range in the memory map. ITIM provides high-performance, predictable instruction delivery. Fetching an instruction from ITIM is as fast as an instruction-cache hit, with no possibility of a cache miss. ITIM can hold data as well as instructions, though loads and stores from a core to its ITIM are not as performant as hits in the D-Cache. Memory requests from one core to any other core's ITIM are not as performant as memory requests from a core to its own ITIM.

The instruction cache can be configured as ITIM for all ways except for 1 in units of cache lines (64 bytes). A single instruction cache way must remain an instruction cache. ITIM is allocated simply by storing to it. A store to the n^{th} byte of the ITIM memory map reallocates the first $n+1$ bytes of instruction cache as ITIM, rounded up to the next cache line.

ITIM is deallocated by storing zero to the first byte after the ITIM region, that is, 28 KiB after the base address of ITIM as indicated in the Memory Map in Chapter 5. The deallocated ITIM space is automatically returned to the instruction cache.

For determinism, software must clear the contents of ITIM after allocating it. It is unpredictable whether ITIM contents are preserved between deallocation and allocation.

4.2 Instruction Fetch Unit

The U54 instruction fetch unit contains branch prediction hardware to improve performance of the processor core. The branch predictor comprises a 30-entry branch target buffer (BTB) which predicts the target of taken branches, a 256-entry branch history table (BHT), which predicts the direction of conditional branches, and a 6-entry return-address stack (RAS) which predicts the target of procedure returns. The branch predictor has a one-cycle latency, so that correctly predicted control-flow instructions result in no penalty. Mispredicted control-flow instructions incur a three-cycle penalty.

The U54 implements the standard Compressed (C) extension to the RISC-V architecture, which allows for 16-bit RISC-V instructions.

4.3 Execution Pipeline

The U54 execution unit is a single-issue, in-order pipeline. The pipeline comprises five stages: instruction fetch, instruction decode and register fetch, execute, data memory access, and register writeback.

The pipeline has a peak execution rate of one instruction per clock cycle, and is fully bypassed so that most instructions have a one-cycle result latency. There are several exceptions:

- LW has a two-cycle result latency, assuming a cache hit.
- LH, LHU, LB, and LBU have a three-cycle result latency, assuming a cache hit.
- CSR reads have a three-cycle result latency.
- MUL, MULH, MULHU, and MULHSU have a 5-cycle result latency.
- DIV, DIVU, REM, and REMU have between a 2-cycle and 65-cycle result latency, depending on the operand values.

The pipeline only interlocks on read-after-write and write-after-write hazards, so instructions may be scheduled to avoid stalls.

The U54 implements the standard Multiply (M) extension to the RISC-V architecture for integer multiplication and division. The U54 has a 16-bit per cycle hardware multiply and a 1-bit per cycle hardware divide.

Branch and jump instructions transfer control from the memory access pipeline stage. Correctly-predicted branches and jumps incur no penalty, whereas mispredicted branches and jumps incur a three-cycle penalty.

Most CSR writes result in a pipeline flush with a five-cycle penalty.

4.4 Data Memory System

The U54 data memory system has a 8-way set-associative 32 KiB write-back data cache that supports 64-byte cache lines. The access latency is two clock cycles for words and double-words, and three clock cycles for smaller quantities. Misaligned accesses are not supported in hardware and result in a trap to support software emulation. The data caches are kept coherent with a directory-based cache coherence manager, which resides in the outer L2 cache.

Stores are pipelined and commit on cycles where the data memory system is otherwise idle. Loads to addresses currently in the store pipeline result in a five-cycle penalty.

4.5 Atomic Memory Operations

The U54 core supports the RISC-V standard Atomic (A) extension on the DTIM and the peripheral memory region. Atomic memory operations to regions that do not support them generate an access exception precisely at the core.

The load-reserved and store-conditional instructions are only supported on cached regions, hence generate an access exception on DTIM and other uncached memory regions.

See *The RISC-V Instruction Set Manual, Volume I: User-Level ISA, Version 2.1* for more information on the instructions added by this extension.

4.6 Floating-Point Unit (FPU)

The U54 FPU provides full hardware support for the IEEE 754-2008 floating-point standard for 32-bit single-precision and 64-bit double-precision arithmetic. The FPU includes a fully pipelined fused-multiply-add unit and an iterative divide and square-root unit, magnitude comparators, and float-to-integer conversion units, all with full hardware support for subnormals and all IEEE default values.

4.7 Virtual Memory Support

The U54 has support for virtual memory through the use of a Memory Management Unit (MMU). The MMU supports the Bare and Sv39 modes as described in *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*.

The U54 MMU has a 39 virtual address space mapped to a 38 physical address space. A hardware page-table walker refills the address translation caches. Both first-level instruction and data address translation caches are fully associative and have 32 entries. There is also a unified second-level translation cache with 128 entries. The MMU supports 2 MiB megapages and 1 GiB gigapages to reduce translation overheads for large contiguous regions of virtual and physical address space.

Note that the U54 does not automatically set the **Accessed** (A) and **Dirty** (D) bits in a Sv39 Page Table Entry (PTE). Instead, the U54 MMU will raise a page fault exception for a read to a page with PTE.A=0 or a write to a page with PTE.D=0.

4.8 Supported Modes

The U54 supports RISC-V supervisor and user modes, providing three levels of privilege: machine (M), supervisor (S) and user (U).

U-mode provides a mechanism to isolate application processes from each other and from trusted code running in M-mode.

S-mode adds a number of additional CSRs and capabilities.

See *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10* for more information on the privilege modes.

4.9 Physical Memory Protection (PMP)

The U54 includes a Physical Memory Protection (PMP) unit compliant with *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*. PMP can be used to set memory access privileges (read, write, execute) for specified memory regions. The U54 PMP supports 8 regions with a minimum region size of 4 bytes.

This section describes how PMP concepts in the RISC-V architecture apply to the U54. The definitive resource for information about the RISC-V PMP is *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*.

4.9.1 Functional Description

The U54 includes a PMP unit, which can be used to restrict access to memory and isolate processes from each other.

The U54 PMP unit has 8 regions and a minimum granularity of 4 bytes. Overlapping regions are permitted. The U54 PMP unit implements the architecturally defined `pmpcfgx` CSR `pmpcfg0` supporting 8 regions. `pmpcfg1`, `pmpcfg2`, and `pmpcfg3` are implemented but hardwired to zero.

The PMP registers may only be programmed in M-mode. Ordinarily, the PMP unit enforces permissions on S-mode and U-mode accesses. However, locked regions (see Section 3.7.2) additionally enforce their permissions on M-mode.

4.9.2 Region Locking

The PMP allows for region locking whereby, once a region is locked, further writes to the configuration and address registers are ignored. Locked PMP entries may only be unlocked with a system reset. A region may be locked by setting the L bit in the `pmplcfg` register.

In addition to locking the PMP entry, the L bit indicates whether the R/W/X permissions are enforced on M-Mode accesses. When the L bit is set, these permissions are enforced for all privilege modes. When the L bit is clear, the R/W/X permissions apply only to U-mode.

4.10 Hardware Performance Monitor

The FU540-C000 supports a basic hardware performance monitoring facility compliant with *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*. The `mcycle` CSR holds a count of the number of clock cycles the hart has executed since some arbitrary time in the past. The `minstret` CSR holds a count of the number of instructions the hart has retired since some arbitrary time in the past. Both are 64-bit counters.

The hardware performance monitor includes two additional event counters, `mhpmcounter3` and `mhpmcounter4`. The event selector CSRs `mhpmevent3` and `mhpmevent4` are registers that control which event causes the corresponding counter to increment. The `mhpmcounters` are 40-bit counters.

The event selectors are partitioned into two fields, as shown in Table 5: the lower 8 bits select an event class, and the upper bits form a mask of events in that class. The counter increments if the event corresponding to any set mask bit occurs. For example, if `mhpmevent3` is set to `0x4200`, then `mhpcounter3` will increment when either a load instruction or a conditional branch instruction retires. Note that an event selector of 0 means "count nothing."

Machine Hardware Performance Monitor Event Register	
Instruction Commit Events, mhpeventX[7:0] = 0	
Bits	Meaning
8	Exception taken
9	Integer load instruction retired
10	Integer store instruction retired
11	Atomic memory operation retired

8	Instruction cache miss
9	Data cache miss or memory-mapped I/O access
10	Data cache writeback
11	Instruction TLB miss
12	Data TLB miss

Table 5: mhpmevent Register Description

4.11 ECC

The U54 Instruction Cache, ITIM, and Data Cache implement Single-Error Correcting and Double-Error Detecting (SECDED) Error Correcting Code. The granularity at which this protection is applied (the codeword) is 32-bit (with an ECC overhead of 7 bits per codeword).

4.11.1 Single Bit Errors

In the case of a single-bit error in the L1 Instruction Cache, the error is corrected, and the cache line is flushed. When a single-bit error is detected in the ITIM, the error is corrected and written back to the SRAM.

When the L1 Data Cache encounters a single-bit error, the Data Cache corrects the error, invalidates the cache line, and writes the line back to the next level of memory hierarchy.

Chapter 5

Memory Map

The memory map of the FU540-C000 is shown in Table 6.

Chapter 6

Boot Process

The FU540-C000 supports booting from several sources, which are controlled using the Mode Select (MSEL[3:0]) pins on the chip. Typically, the boot process runs through several stages before it begins execution of user-provided programs. These stages typically include the following:

1. Zeroth Stage Boot Loader (ZSBL), which is contained in an on-chip mask ROM
2. First Stage Boot Loader (FSBL), which brings up PLLs and DDR memory; described is the default SiFive-provided FSBL for this chip
3. Berkeley Boot Loader (BBL), which adds emulation for soft instructions; described is the default SiFive-provided BBL used at product launch
4. User Payload, which contains the software to run, typically Linux

Both the ZSBL and FSBL download the next stage boot loader based on the MSEL setting. All possible values are enumerated in Table 7. The three QSPI interfaces on the FU540-C000 can be used to download media either from SPI flash (using x4 data pins or x1) or an SD card, using the SPI protocol. These boot methods are detailed at the end of this chapter.

MSEL	FSBL	BBL	Purpose
0000	-	-	loops forever waiting for debugger
0001	-	-	jump directly to 0x2000_0000 (memory-mapped QSPI0)
0010	-	-	jump directly to 0x3000_0000 (memory-mapped QSPI1)
0011	-	-	jump directly to 0x4000_0000 (uncached ChipLink)
0100	-	-	jump directly to 0x6000_0000 (cached ChipLink)
0101	QSPI0 x1	QSPI0 x1	-
0110	QSPI0 x4	QSPI0 x4	Rescue image from flash (preprogrammed)
0111	QSPI1 x4	QSPI1 x4	-
1000	QSPI1 SD	QSPI1 SD	-
1001	QSPI2 x1	QSPI2 x1	-
1010	QSPI0 x4	QSPI1 SD	-
1011	QSPI2 SD	QSPI2 SD	Rescue image from SD card
1100	QSPI1 x1	QSPI2 SD	-
1101	QSPI1 x4	QSPI2 SD	-
1110	QSPI0 x1	QSPI2 SD	-
1111	QSPI0 x4	QSPI2 SD	Default boot mode

Table 7: Boot media used by ZSBL and FSBL dependinf on Mode Select (MSEL)

6.1 Reset Vector

On power-on, all cores jump to 0x1004 while running directly off of the external clock input, expected to be 33.3 MHz. The memory at this location contains:

Address	Contents
0x1000	The MSEL pin state
0x1004	auipc t0, 0
0x1008	lw t1, -4(t0)
0x100C	slli t1, t1, 0x3
0x1010	add t0, t0, t1
0x1014	lw t0, 252(t0)

1001	0x0001_0000	ZSBL
1010	0x0001_0000	ZSBL
1011	0x0001_0000	ZSBL
1100	0x0001_0000	ZSBL
1101	0x0001_0000	ZSBL
1110	0x0001_0000	ZSBL
1111	0x0001_0000	ZSBL

Table 9: Target of the reset vector

6.2 Zeroth Stage Boot Loader (ZSBL)

The Zeroth Stage Boot Loader (ZSBL) is contained in a mask ROM at 0x1_0000. It is responsible for downloading the more complicated FSBL from a GUID Partition Table. All cores enter the ZSBL running directly off of the external clock input, expected to be at 33.3 MHz. The core with

mhartid zero configures the peripheral clock dividers and then searches for a partition with GUID type 5B193300-FC78-40CD-8002-E86C45580B47. It does this by first downloading the GPT header (bytes 512-604) and then sequentially scanning the partition table block by block (512 bytes) until the partition is found. Then, the entire contents of this partition, the FSBL, are downloaded into the L2 LIM at address 0x0800_0000. Execution then branches to the FSBL.

The ZSBL uses the MSEL pins to determine where to look for the FSBL partition:

MSEL	FSBL location	Method	Width
0101	QSPI0 flash	memory-mapped	x1
0110	QSPI0 flash	memory-mapped	x4
0111	QSPI1 flash	memory-mapped	x4
1000	QSPI1 SD card	bit-banged	x1
1001	QSPI2 flash	bit-banged	x1
1010	QSPI0 flash	memory-mapped	x4
1011	QSPI2 SD card	bit-banged	x1
1100	QSPI1 flash	bit-banged	x1
1101	QSPI1 flash	memory-mapped	x4
1110	QSPI0 flash	bit-banged	x1
1111	QSPI0 flash	memory-mapped	x4

Table 10: FSBL location downloaded by the ZSBL

6.3 First Stage Boot Loader (FSBL)

The First Stage Boot Loader (FSBL) is executed from the L2 LIM, located at 0x0800_0000. It is responsible for preparing the system to run from DDR. It performs these operations:

- Switch core frequency to 1 GHz (or 500 MHz if TLCLKSEL=1) by configuring and running off the on-chip PLL
- Configure DDR PLL, PHY, and controller
- Set GEM GXL TX PLL to 125 MHz and reset it
- If there is an external PHY, reset it
- Download BBL from a partition with GUID type 2E54B353-1271-4842-806F-E436D6AF69851
- Scan the OTP for the chip serial number
- Copy the embedded DTB to DDR, filling in FSBL version, memory size, and MAC address
- Enable 15 of the 16 L2 ways (this removes almost all of the L2 LIM memory)
- Jump to DDR memory (0x8000_0000)

The FSBL reads the MSEL switches to determine where to look for the BBL partition:

MSEL	BBL location	Method	Width
0101	QSPI0 flash	memory-mapped	x1
0110	QSPI0 flash	memory-mapped	x4
0111	QSPI1 flash	memory-mapped	x4
1000	QSPI1 SD card	bit-banged	x1
1001	QSPI2 flash	bit-banged	x1
1010	QSPI1 SD card	bit-banged	x1
1011	QSPI2 SD card	bit-banged	x1
1100	QSPI2 SD card	bit-banged	x1
1101	QSPI2 SD card	bit-banged	x1
1110	QSPI2 SD card	bit-banged	x1
1111	QSPI2 SD card	bit-banged	x1

Table 11: BBL location downloaded by the FSBL

6.4 Berkeley Boot Loader (BBL)

The Berkeley Boot Loader (BBL) is executed from DDR, located at 0x8000_0000. It is responsible for providing the Supervisor Binary Interface (SBI) as well as emulating any RISC-V required instructions that are not implemented by the chip itself. At the time of writing, BBL often includes an embedded Linux kernel payload that it jumps to once the SBI is initialized.

6.5 Boot Methods

Both the ZSBL and FSBL download the next stage boot-loader from a QSPI interface. However, the protocol used varies depending on MSEL. The details of these boot methods are detailed here.

6.5.1 Flash Bit-Banged x1

When using the flash bit-banged boot method, the firmware switches the QSPI controller out of flash memory-mapped mode and sends SPI commands directly to the controller. In this mode, the QSPI interface is clocked no higher than 10 MHz. When the core is running at 33.3 MHz, this means 8.3 MHz. At 1 GHz, this means exactly 10 MHz.

The firmware first sends commands RESET_ENABLE (0x66) and RESET (0x99). To download data required during GPT parsing and partition payload, it uses READ (0x03) with a 3-byte address and no dummy cycles. Data is streamed continuously for the entire transfer. This means that partitions needed during boot must be located within the low 16 MiB of the flash.

6.5.2 Flash Memory-Mapped x1

When using the flash memory-mapped x1 boot method, the firmware uses the QSPI controller's hardware SPI flash read support. In this mode, the QSPI interface is clocked no higher than 10 MHz. When the core is running at 33.3 MHz, this means 8.3 MHz. At 1 GHz, this means exactly 10 MHz.

The firmware first manually runs RESET_ENABLE (0x66) and RESET (0x99). To download data required during GPT parsing and partition payload, it uses memcpy from the memory-mapped QSPI region. The QSPI controller is configured so that hardware flash interfaces uses READ (0x03) with a 3-byte address and no dummy cycles. Data is streamed continuously for the entire transfer. This means that partitions needed during boot must be located within the low 16 MiB of the flash.

6.5.3 Flash Memory-Mapped x4

When using the flash memory-mapped x4 boot method, the firmware uses the QSPI controller's hardware SPI flash read support. In this mode, the QSPI interface is clocked no higher than 10 MHz. When the core is running at 33.3 MHz, this means 8.3 MHz. At 1 GHz, this means exactly 10 MHz.

The firmware first manually runs RESET_ENABLE (0x66) and RESET (0x99). To download data required during GPT parsing and partition payload, it uses memcpy from the memory-mapped QSPI region. The QSPI controller is configured so that hardware flash interfaces uses FAST_READ_QUAD_OUTPUT (0x6b) with a 3-byte address and 8 dummy cycles. Data is streamed continuously for the entire transfer. This means that partitions needed during boot must be located within the low 16 MiB of the flash.

6.5.4 SD Card Bit-Banged x1

When using the SD card boot method, the firmware performs these initialization steps:

1. Wait 1 ms before initiating commands.
2. Set the QSPI controller to 400 kHz.
3. Send 10 SPI clock pulses with CS inactive.
4. Send CMD0, CMD8, ACMD41, CMD58, CMD16.
5. Set the QSPI controller to 20 MHz.

To download data required during GPT parsing and partition payload, it uses the READ_BLOCK_MULTIPLE (18) command. Data is streamed continuously for the entire transfer.

Chapter 7

Clocking and Reset

This chapter describes the clocking and reset operation of the FU540-C000.

Clocking and reset is managed by the PRCI (Power Reset Clocking Interrupt) block (Figure 2).

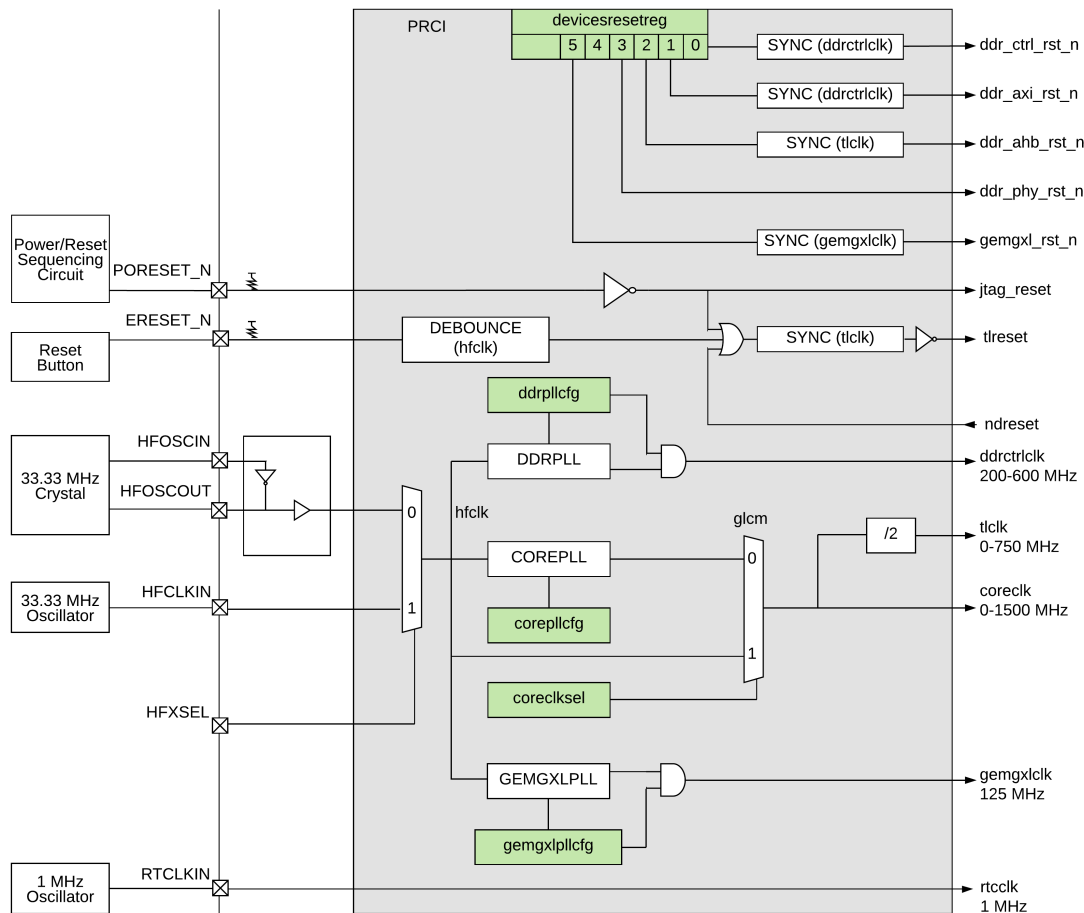

Figure 2: Clocking and Reset Architecture

7.1 Clocking

FU540-C000 generates all internal clocks from 33.33 MHz `hfc1k` driven from an external oscillator (`HFCLKIN`) or crystal (`HFOSCIN`) input, selected by input `HFXSEL`.

All harts operate in a single clock domain (`corec1k`) supplied by a single PLL, which steps 33.33 MHz `hfc1k` up to higher frequencies. The recommended frequency of `corec1k` is 1.0 GHz, however operation at upto 1.5 GHz is possible.

The L2 cache and peripherals such as UART, SPI, I2C, and PWM operate in a single clock domain (`tlc1k`) running at `corec1k/2` rate. There is a low-latency 2:1 crossing between `corec1k` and `tlc1k` domains.

The DDR and Ethernet Subsystems operate asynchronously. The PRCI contains two dedicated PLLs used to step 33.33 MHz `hfc1k` up to their operating frequencies.

The PRCI contains memory-mapped registers that control the clock selection and configuration of the PLLs. On power-on, the default PRCI register settings start the harts running directly from `hfc1k`. All additional clock management, for instance initializing the DDR PLL or stepping the `corec1k` frequency, is performed through software reads and writes to the memory-mapped PRCI control registers.

The CPU real time clock (`rtcc1k`) runs at 1 MHz and is driven from input pin `RTCCLKIN`. This should be connected to an external oscillator.

JTAG debug logic runs off of JTAG TCK as described in Chapter 23.

7.2 Reset

The FU540-C000 has two external reset pins.

`PORESET_N` is an asynchronous active low power-on reset that should be connected to an external power sequencing/supervisory circuit.

`ERESET_N` is an asynchronous active low reset that can be connected to a reset button. There is internal debounce and stretch logic.

The PRCI contains hardware to generate internal synchronous resets for `corec1k` and `tlc1k` domains and handle reset to and from the debug module. Reset for the DDR and Ethernet Subsystems is performed through software reads and writes to memory-mapped PRCI control registers.

7.3 Memory Map (0x1000_0000–0x1000_0FFF)

This section presents an overview of the PRCI control and configuration registers.

Crystal Input Control Register (hfxosccfg)

Table 19: Peripheral Devices Reset Control Register

7.4 Reset and Clock Initialization

7.4.1 Power-On

1. The PCB should strap input signal HFXSEL to set the 33.33 MHz hfc1k clock source. To use a Crystal clock source connected to pins HFXOSCIN and HFXOSCOU, connect HFXSEL to GND. To use an Oscillator clock source connected to HFXCLKIN, connect HFXSEL to VCC.
2. At power-on, PORESET_N should be asserted by an external power sequencing/supervisory circuit. After power-ramp and valid hfc1k, PORESET_N should be driven low for a minimum of 10 ns.
3. Harts begin the Boot Flow described in Chapter 6, running at 33.33 MHz hfc1k.

7.4.2 Setting corec1k frequency

1. COREPLL Setup

COREPLL is configured in software by setting the corepllcfg0 PRCI control register. The input reference frequency for COREPLL is 33.33 MHz.

There is a reference frequency divider before the PLL loop. The divider value is equal to PRCI PLL configuration register field `divr` + 1. The minimum supported post-divide frequency is 7 MHz; thus, valid settings are 0, 1, and 2.

The valid PLL VCO range is 2400 MHz to 4800 MHz. The VCO feedback divider value is equal to $2 \times (\text{divf} + 1)$.

There is a further output divider after the PLL loop. The divider value is equal to 2^{divq} . The maximum value of DIVQ is 6, and the valid output range is 20 to 2400 MHz.

For example, to setup COREPLL for 1 GHz operation, program `divr = 0 (x1)`, `divf = 59 (4000 MHz VCO)`, `divq = 2 (/4 Output divider)`.

2. Wait for Lock

Poll PRCI PLL configuration register field `lock` to wait for PLL lock.

3. Switch `coreclk` from 33 MHz `hfc1k` to COREPLL

A glitch-free clock mux (GLCM) switches the driver of `coreclk` between `hfc1k` and COREPLL at runtime, under control of the PRCI control register `coreclkse1`. Setting CORECLKSEL equal to 0 selects COREPLL output.

7.4.3 DDR and Ethernet Subsystem Clocking and Reset

The active-low, synchronous resets for the DDR and Ethernet subsystem are connected via clock domain synchronizers to the PRCI Devices Reset Control Register (`devicesresetreg`).

On power-on, this register is set to zero holding both blocks in reset. Clocking and Reset is initialized in the First Stage Boot Loader (FSBL).

1. DDRPLL and GEMGXLPLL Setup

The DDR and Ethernet subsystem input clocks are driven from DDRPLL and GEMGXLPLL in the PRCI. The two PLLs are programmed as per COREPLL using steps 1 and 2 listed above. GEMGXLPLL is set up for 125 MHz output frequency. `divr = 0`, `divf = 59 (4000 MHz VCO)`, `divq = 5` DDRPLL is set up to run at the memory MT/s divided by 4.

2. Wait for lock

Poll PRCI PLL configuration register field `lock` to wait for PLL lock.

3. Release Clock Gate

Both PLLs have an additional glitch-free clock gate on output controlled by PRCI PLL configuration register field `cke`. This gate prevents runt pulses from clocking these complex IPs during PLL lock. After PLL lock, the clock gate is released by setting `CKE` to 1.

4. Release Reset

After the clock is initialized, synchronous reset is released by setting the appropriate bits in the PRCI Peripheral Devices Reset Control Register (`devicesresetreg`) to 1.

GEMGXL reset is released by setting PRCI Devices Reset Control Register (`devicesresetreg`) field `gemgx1_rst_n` to 1. The complete reset sequence for the DDR Subsystem is documented in Chapter 20.

Chapter 8

Interrupts

This chapter describes how interrupt concepts in the RISC-V architecture apply to the FU540-C000. The definitive resource for information about the RISC-V interrupt architecture is *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*.

8.1 Interrupt Concepts

FU540-C000 has support for the following interrupts: local (including software and timer) and global.

Local interrupts are signaled directly to an individual hart with a dedicated interrupt value. This allows for reduced interrupt latency as no arbitration is required to determine which hart will service a given request and no additional memory accesses are required to determine the cause of the interrupt. Software and timer interrupts are local interrupts generated by the Core Local Interruptor (CLINT). The FU540-C000 contains no other local interrupt sources.

Global interrupts, by contrast, are routed through a Platform-Level Interrupt Controller (PLIC), which can direct interrupts to any hart in the system via the external interrupt. Decoupling global interrupts from the hart(s) allows the design of the PLIC to be tailored to the platform, permitting a broad range of attributes like the number of interrupts and the prioritization and routing schemes.

By default, all interrupts are handled in machine mode. For harts that support supervisor mode, it is possible to selectively delegate interrupts to supervisor mode.

This chapter describes the FU540-C000 interrupt architecture. Chapter 9 describes the Core Local Interruptor. Chapter 10 describes the global interrupt architecture and the PLIC design.

The FU540-C000 interrupt architecture is depicted in Figure 3.

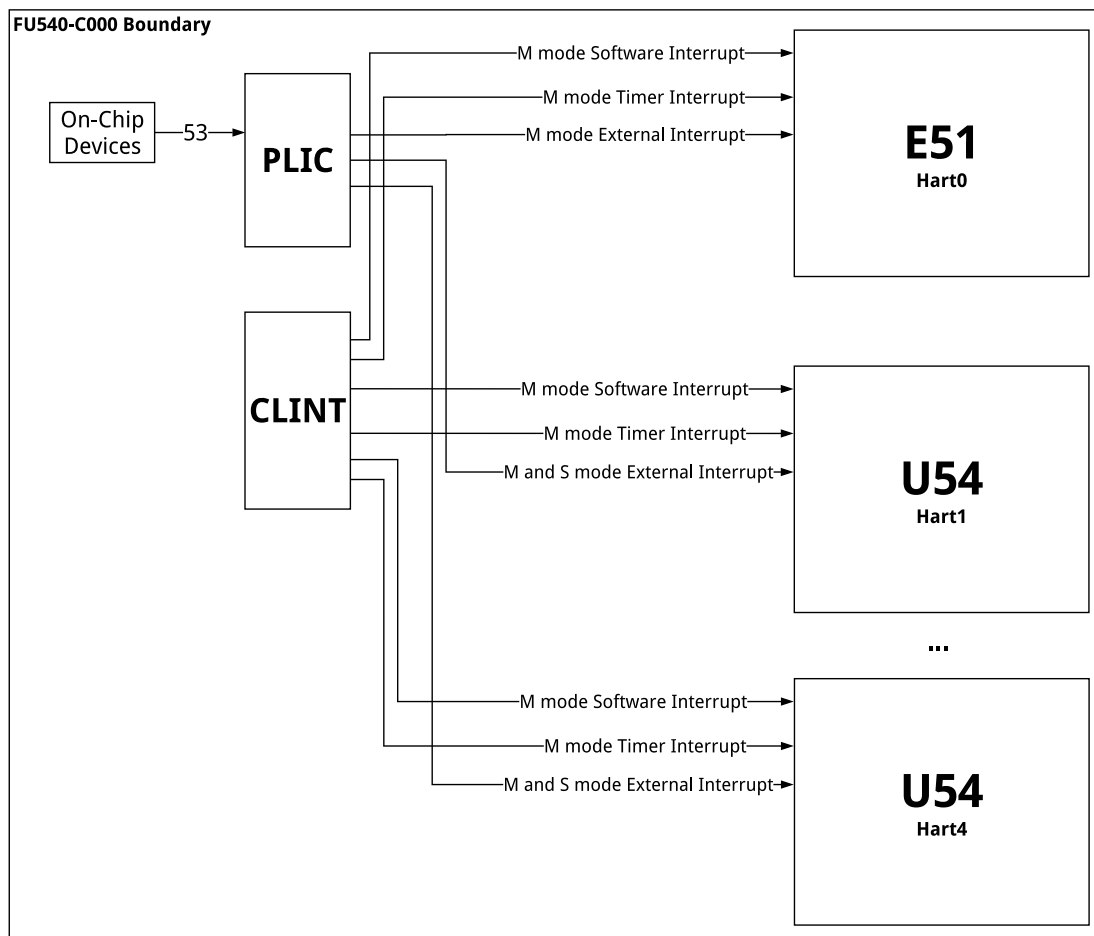

Figure 3: FU540-C000 Interrupt Architecture Block Diagram.

8.2 Interrupt Entry and Exit

When a RISC-V hart takes an interrupt, the following occurs:

- The value of `mstatus.MIE` is copied into `mstatus.MPIE`, and then `mstatus.MIE` is cleared, effectively disabling interrupts.
- The current `pc` is copied into the `mepc` register, and then `pc` is set to the value of `mtvec`. In the case where vectored interrupts are enabled, `pc` is set to `mtvec.BASE + 4 × exception code`.
- The privilege mode prior to the interrupt is encoded in `mstatus.MPP`.

At this point, control is handed over to software in the interrupt handler with interrupts disabled. Interrupts can be re-enabled by explicitly setting `mstatus.MIE` or by executing an `MRET` instruction to exit the handler. When an `MRET` instruction is executed, the following occurs:

- The privilege mode is set to the value encoded in `mstatus.MPP`.

- The value of `mstatus.MPIE` is copied into `mstatus.MIE`.
- The `pc` is set to the value of `mepc`.

At this point control is handed over to software.

The Control and Status Registers involved in handling RISC-V interrupts are described in Section 8.3

8.3 Interrupt Control Status Registers

The FU540-C000 specific implementation of interrupt CSRs is described below. For a complete description of RISC-V interrupt behavior and how to access CSRs, please consult *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*.

8.3.1 Machine Status Register (`mstatus`)

The `mstatus` register keeps track of and controls the hart's current operating state, including whether or not interrupts are enabled. A summary of the `mstatus` fields related to interrupts in the FU540-C000 is provided in Table 20. Note that this is not a complete description of `mstatus` as it contains fields unrelated to interrupts. For the full description of `mstatus`, please consult the *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*.

Machine Status Register			
CSR	mstatus		
Bits	Field Name	Attr.	Description
0	Reserved	WPRI	
1	SIE	RW	Supervisor Interrupt Enable
2	Reserved	WPRI	
3	MIE	RW	Machine Interrupt Enable
4	Reserved	WPRI	
5	SPIE	RW	Supervisor Previous Interrupt Enable
6	Reserved	WPRI	
7	MPIE	RW	Machine Previous Interrupt Enable
8	SPP	RW	Supervisor Previous Privilege Mode
[10:9]	Reserved	WPRI	
[12:11]	MPP	RW	Machine Previous Privilege Mode

Table 20: FU540-C000 `mstatus` Register (partial)

Interrupts are enabled by setting the MIE bit in `mstatus` and by enabling the desired individual interrupt in the `mie` register, described in Section 8.3.2.

8.3.2 Machine Interrupt Enable Register (mie)

Individual interrupts are enabled by setting the appropriate bit in the mie register. The mie register is described in Table 21.

Machine Interrupt Enable Register			
CSR	mie		
Bits	Field Name	Attr.	Description
0	Reserved	WPRI	
1	SSIE	RW	Supervisor Software Interrupt Enable
2	Reserved	WPRI	
3	MSIE	RW	Machine Software Interrupt Enable
4	Reserved	WPRI	
5	STIE	RW	Supervisor Timer Interrupt Enable
6	Reserved	WPRI	
7	MTIE	RW	Machine Timer Interrupt Enable
8	Reserved	WPRI	
9	SEIE	RW	Supervisor External Interrupt Enable
10	Reserved	WPRI	
11	MEIE	RW	Machine External Interrupt Enable
[63:12]	Reserved	WPRI	

Table 21: mie Register

8.3.3 Machine Interrupt Pending (mip)

The machine interrupt pending (mip) register indicates which interrupts are currently pending. The mip register is described in Table 22.

Machine Interrupt Pending Register			
CSR	mip		
Bits	Field Name	Attr.	Description
0	Reserved	WIRI	
1	SSIP	RW	Supervisor Software Interrupt Pending
2	Reserved	WIRI	
3	MSIP	RO	Machine Software Interrupt Pending
4	Reserved	WIRI	
5	STIP	RW	Supervisor Timer Interrupt Pending
6	Reserved	WIRI	
7	MTIP	RO	Machine Timer Interrupt Pending
8	Reserved	WIRI	
9	SEIP	RW	Supervisor External Interrupt Pending
10	Reserved	WIRI	
11	MEIP	RO	Machine External Interrupt Pending
[63:12]	Reserved	WIRI	

Table 22: mip Register

8.3.4 Machine Cause Register (mcause)

When a trap is taken in machine mode, mcause is written with a code indicating the event that caused the trap. When the event that caused the trap is an interrupt, the most-significant bit of mcause is set to 1, and the least-significant bits indicate the interrupt number, using the same encoding as the bit positions in mip. For example, a Machine Timer Interrupt causes mcause to be set to 0x8000_0000_0000_0007. mcause is also used to indicate the cause of synchronous exceptions, in which case the most-significant bit of mcause is set to 0. See Table 23. Refer to Table 24 for a list of synchronous exception codes.

Machine Cause Register			
CSR	mcause		
Bits	Field Name	Attr.	Description
[62:0]	Exception Code	WLRL	A code identifying the last exception.
63	Interrupt	WARL	1 if the trap was caused by an interrupt; 0 otherwise.

0	5	Load access fault
0	6	Store/AMO address misaligned
0	7	Store/AMO access fault
0	8	Environment call from U-mode
0	9	Environment call from S-mode
0	10	Reserved
0	11	Environment call from M-mode
0	12	Instruction page fault
0	13	Load page fault
0	14	Reserved
0	15	Store/AMO page fault
0	≥ 16	Reserved

Table 24: mcause Exception Codes

8.3.5 Machine Trap Vector (mtvec)

By default, all interrupts trap to a single address defined in the `mtvec` register. It is up to the interrupt handler to read `mcause` and react accordingly. RISC-V and the FU540-C000 also support the ability to optionally enable interrupt vectors. When vectoring is enabled, each interrupt defined in `mie` will trap to its own specific interrupt handler. This allows all local interrupts to trap to exclusive handlers. Even with vectoring enabled, all global interrupts will trap to the same global interrupt vector.

Vectored interrupts are enabled when the `MODE` field of the `mtvec` register is set to 1.

Machine Trap Vector Register			
CSR	mtvec		
Bits	Field Name	Attr.	Description
[1:0]	MODE	WARL	MODE determines whether or not interrupt vectoring is enabled. The encoding for the MODE field is described in Table 26.
[63:2]	BASE[63:2]	WARL	Interrupt Vector Base Address. Must be aligned on a 128-byte boundary when MODE=1. Note, BASE[1:0] is not present in this register and is implicitly 0.

Table 25: mtvec Register

MODE Field Encoding mtvec.MODE		
Value	Name	Description
0	Direct	All exceptions set pc to BASE
1	Vectored	Asynchronous interrupts set pc to BASE + 4 × cause.
≥ 2	Reserved	

Table 26: Encoding of mtvec.MODE

If vectored interrupts are disabled (mtvec.MODE = 0), all interrupts trap to the mtvec.BASE address. If vectored interrupts are enabled (mtvec.MODE = 1), interrupts set the pc to mtvec.BASE + 4 × exception code. For example, if a machine timer interrupt is taken, the pc is set to mtvec.BASE + 0x1C. Typically, the trap vector table is populated with jump instructions to transfer control to interrupt-specific trap handlers.

In vectored interrupt mode, BASE must be 128-byte aligned.

All machine external interrupts (global interrupts) are mapped to exception code of 11. Thus, when interrupt vectoring is enabled, the pc is set to address mtvec.BASE + 0x2C for any global interrupt.

See Table 25 for a description of the mtvec register. See Table 26 for a description of the mtvec.MODE field. See Table 24 for the FU540-C000 interrupt exception code values.

8.4 Supervisor Mode Interrupts

The FU540-C000 supports the ability to selectively direct interrupts and exceptions to supervisor mode, resulting in improved performance by eliminating the need for additional mode changes.

This capability is enabled by the interrupt and exception delegation CSRs; mideleg and medeleg, respectively. Supervisor interrupts and exceptions can be managed via supervisor versions of the interrupt CSRs, specifically: stvec, sip, sie, and scause.

Machine mode software can also directly write to the `sip` register, which effectively sends an interrupt to supervisor mode. This is especially useful for timer and software interrupts as it may be desired to handle these interrupts in both machine mode and supervisor mode.

The delegation and supervisor CSRs are described in the sections below. The definitive resource for information about RISC-V supervisor interrupts is *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*.

8.4.1 Delegation Registers (`m*deleg`)

By default, all traps are handled in machine mode. Machine mode software can selectively delegate interrupts and exceptions to supervisor mode by setting the corresponding bits in `mideleg` and `medeleg` CSRs. The exact mapping is provided in Table 27 and Table 28 and matches the `mcause` interrupt and exception codes defined in Table 24.

Note that local interrupts can not be delegated to supervisor mode.

Machine Interrupt Delegation Register			
CSR	mideleg		
Bits	Field Name	Attr.	Description
0	Reserved	WARL	
1	MSIP	RW	Delegate Supervisor Software Interrupt
[4:2]	Reserved	WARL	
5	MTIP	RW	Delegate Supervisor Timer Interrupt
[8:6]	Reserved	WARL	
9	MEIP	RW	Delegate Supervisor External Interrupt
[63:10]	Reserved	WARL	

Table 27: `mideleg` Register

Machine Exception Delegation Register			
CSR	medeleg		
Bits	Field Name	Attr.	Description
0		RW	Delegate Instruction Access Misaligned Exception
1		RW	Delegate Instruction Access Fault Exception
2		RW	Delegate Illegal Instruction Exception
3		RW	Delegate Breakpoint Exception
4		RW	Delegate Load Access Misaligned Exception
5		RW	Delegate Load Access Fault Exception
6		RW	Delegate Store/AMO Address Misaligned Exception
7		RW	Delegate Store/AMO Access Fault Exception
8		RW	Delegate Environment Call from U-Mode
9		RW	Delegate Environment Call from S-Mode
[11:0]	Reserved	WARL	
12		RW	Delegate Instruction Page Fault
13		RW	Delegate Load Page Fault
14	Reserved	WARL	
15		RW	Delegate Store/AMO Page Fault Exception
[63:16]	Reserved	WARL	

Table 28: medeleg Register

8.4.2 Supervisor Status Register (sstatus)

Similar to machine mode, supervisor mode has a register dedicated to keeping track of the hart's current state called `sstatus`. `sstatus` is effectively a restricted view of `mstatus`, described in Section 8.3.1, in that changes made to `sstatus` are reflected in `mstatus` and vice-versa, with the exception of the machine mode fields, which are not visible in `sstatus`.

A summary of the `sstatus` fields related to interrupts in the FU540-C000 is provided in Table 29. Note that this is not a complete description of `sstatus` as it also contains fields unrelated to interrupts. For the full description of `sstatus`, consult the *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*.

Supervisor Status Register			
CSR	sstatus		
Bits	Field Name	Attr.	Description
0	Reserved	WPRI	
1	SIE	RW	Supervisor Interrupt Enable
[4:2]	Reserved	WPRI	
5	SPIE	RW	Supervisor Previous Interrupt Enable
[7:6]	Reserved	WPRI	
8	SPP	RW	Supervisor Previous Privilege Mode
[12:9]	Reserved	WPRI	

Table 29: FU540-C000 sstatus Register (partial)

Interrupts are enabled by setting the SIE bit in sstatus and by enabling the desired individual interrupt in the sie register, described in Section 8.4.3.

8.4.3 Supervisor Interrupt Enable Register (sie)

Supervisor interrupts are enabled by setting the appropriate bit in the sie register. The FU540-C000 sie register is described in Table 30.

Supervisor Interrupt Enable Register			
CSR	sie		
Bits	Field Name	Attr.	Description
0	Reserved	WPRI	
1	SSIE	RW	Supervisor Software Interrupt Enable
[4:2]	Reserved	WPRI	
5	STIE	RW	Supervisor Timer Interrupt Enable
[8:6]	Reserved	WPRI	
9	SEIE	RW	Supervisor External Interrupt Enable
[63:10]	Reserved	WPRI	

Table 30: sie Register

8.4.4 Supervisor Interrupt Pending (sip)

The supervisor interrupt pending (sip) register indicates which interrupts are currently pending. The FU540-C000 sip register is described in Table 31.

Supervisor Interrupt Pending Register			
CSR	sip		
Bits	Field Name	Attr.	Description
0	Reserved	WIRI	
1	SSIP	RW	Supervisor Software Interrupt Pending
[4:2]	Reserved	WIRI	
5	STIP	RW	Supervisor Timer Interrupt Pending
[8:6]	Reserved	WIRI	
9	SEIP	RW	Supervisor External Interrupt Pending
[63:10]	Reserved	WIRI	

Table 31: sip Register

8.4.5 Supervisor Cause Register (scause)

When a trap is taken in supervisor mode, scause is written with a code indicating the event that caused the trap. When the event that caused the trap is an interrupt, the most-significant bit of scause is set to 1, and the least-significant bits indicate the interrupt number, using the same encoding as the bit positions in sip. For example, a Supervisor Timer Interrupt causes scause to be set to 0x8000_0000_0000_0005.

scause is also used to indicate the cause of synchronous exceptions, in which case the most-significant bit of scause is set to 0. Refer to Table 33 for a list of synchronous exception codes.

Supervisor Cause Register			
CSR	scause		
Bits	Field Name	Attr.	Description
[62:0]	Exception Code	WLRL	A code identifying the last exception.
63	Interrupt	WARL	1 if the trap was caused by an interrupt; 0 otherwise.

Table 32: scause Register

Supervisor Interrupt Exception Codes		
Interrupt	Exception Code	Description
1	0	Reserved
1	1	Supervisor software interrupt
1	2 – 4	Reserved
1	5	Supervisor timer interrupt
1	6 – 8	Reserved
1	9	Supervisor external interrupt
1	≥ 10	Reserved
0	0	Instruction address misaligned
0	1	Instruction access fault
0	2	Illegal instruction
0	3	Breakpoint
0	4	Reserved
0	5	Load access fault
0	6	Store/AMO address misaligned
0	7	Store/AMO access fault
0	8	Environment call from U-mode
0	9 – 11	Reserved
0	12	Instruction page fault
0	13	Load page fault
0	14	Reserved
0	15	Store/AMO Page Fault
0	≥ 16	Reserved

Table 33: scause Exception Codes

8.4.6 Supervisor Trap Vector (stvec)

By default, all interrupts trap to a single address defined in the `stvec` register. It is up to the interrupt handler to read `scause` and react accordingly. RISC-V and the FU540-C000 also support the ability to optionally enable interrupt vectors. When vectoring is enabled, each interrupt defined in `sie` will trap to its own specific interrupt handler.

Vectored interrupts are enabled when the `MODE` field of the `stvec` register is set to 1.

Supervisor Trap Vector Register			
CSR	stvec		
Bits	Field Name	Attr.	Description
[1:0]	MODE	WARL	MODE determines whether or not interrupt vectoring is enabled. The encoding for the MODE field is described in Table 35.
[63:2]	BASE[63:2]	WARL	Interrupt Vector Base Address. Must be aligned on a 128-byte boundary when MODE=1. Note, BASE[1:0] is not present in this register and is implicitly 0.

Table 34: stvec Register

MODE Field Encoding stvec.MODE		
Value	Name	Description
0	Direct	All exceptions set pc to BASE
1	Vectored	Asynchronous interrupts set pc to BASE + 4 × cause.
≥ 2	Reserved	

Table 35: Encoding of stvec.MODE

If vectored interrupts are disabled (`stvec.MODE=0`), all interrupts trap to the `stvec.BASE` address. If vectored interrupts are enabled (`stvec.MODE=1`), interrupts set the pc to `stvec.BASE + 4 × exception code`. For example, if a supervisor timer interrupt is taken, the pc is set to `stvec.BASE + 0x14`. Typically, the trap vector table is populated with jump instructions to transfer control to interrupt-specific trap handlers.

In vectored interrupt mode, BASE must be 128-byte aligned.

All supervisor external interrupts (global interrupts) are mapped to exception code of 9. Thus, when interrupt vectoring is enabled, the pc is set to address `stvec.BASE + 0x24` for any global interrupt.

See Table 34 for a description of the stvec register. See Table 35 for a description of the stvec.MODE field. See Table 33 for the FU540-C000 supervisor mode interrupt exception code values.

8.4.7 Delegated Interrupt Handling

Upon taking a delegated trap, the following occurs:

- The value of `sstatus.SIE` is copied into `sstatus.SPIE`, then `sstatus.SIE` is cleared, effectively disabling interrupts.

- The current pc is copied into the sepc register, and then pc is set to the value of stvec. In the case where vectored interrupts are enabled, pc is set to `stvec.BASE + 4 × exception code`.
- The privilege mode prior to the interrupt is encoded in `sstatus.SPP`.

At this point, control is handed over to software in the interrupt handler with interrupts disabled. Interrupts can be re-enabled by explicitly setting `sstatus.SIE` or by executing an SRET instruction to exit the handler. When an SRET instruction is executed, the following occurs:

- The privilege mode is set to the value encoded in `sstatus.SPP`.
- The value of `sstatus.SPIE` is copied into `sstatus.SIE`.
- The pc is set to the value of sepc.

At this point, control is handed over to software.

8.5 Interrupt Priorities

Individual priorities of global interrupts are determined by the PLIC, as discussed in Chapter 10.

FU540-C000 interrupts are prioritized as follows, in decreasing order of priority:

- Machine external interrupts
- Machine software interrupts
- Machine timer interrupts
- Supervisor external interrupts
- Supervisor software interrupts
- Supervisor timer interrupts

8.6 Interrupt Latency

Interrupt latency for the FU540-C000 is 4 cycles, as counted by the numbers of cycles it takes from signaling of the interrupt to the hart to the first instruction fetch of the handler.

Global interrupts routed through the PLIC incur additional latency of 3 cycles where the PLIC is clocked by `t1Clk`. This means that the total latency, in cycles, for a global interrupt is: $4 + 3 \times (\text{coreClk Hz} \div \text{t1Clk Hz})$. This is a best case cycle count and assumes the handler is cached or located in ITIM. It does not take into account additional latency from a peripheral source.

Additionally, the hart will not abandon a Divide instruction in flight. This means if an interrupt handler tries to use a register that is the destination register of a divide instruction the pipeline stalls until the divide is complete.

Chapter 9

Core Local Interruptor (CLINT)

The CLINT block holds memory-mapped control and status registers associated with software and timer interrupts. The FU540-C000 CLINT complies with *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*.

9.1 CLINT Memory Map

Table 36 shows the memory map for CLINT on SiFive FU540-C000.

Address	Width	Attr.	Description	Notes
0x200000	4B	RW	msip for hart 0	MSIP Registers (1 bit wide)

0x20c000			Reserved	

Table 36: CLINT Register Map

9.2 MSIP Registers

Machine-mode software interrupts are generated by writing to the memory-mapped control register `msip`. Each `msip` register is a 32-bit wide **WARL** register where the upper 31 bits are tied to 0. The least significant bit is reflected in the MSIP bit of the `mip` CSR. Other bits in the `msip` registers are hardwired to zero. On reset, each `msip` register is cleared to zero.

Software interrupts are most useful for interprocessor communication in multi-hart systems, as harts may write each other's `msip` bits to effect interprocessor interrupts.

9.3 Timer Registers

`mtime` is a 64-bit read-write register that contains the number of cycles counted from the RTCCLK input described in Chapter 7. A timer interrupt is pending whenever `mtime` is greater than or equal to the value in the `mtimecmp` register. The timer interrupt is reflected in the `mtip` bit of the `mip` register described in Chapter 8.

On reset, `mtime` is cleared to zero. The `mtimecmp` registers are not reset.

9.4 Supervisor Mode Delegation

By default, all interrupts trap to machine mode, including timer and software interrupts. In order for supervisor timer and software interrupts to trap directly to supervisor mode, supervisor timer and software interrupts must first be delegated to supervisor mode.

Please see Section 8.4 for more details on supervisor mode interrupts.

Chapter 10

Platform-Level Interrupt Controller (PLIC)

This chapter describes the operation of the platform-level interrupt controller (PLIC) on the FU540-C000. The PLIC complies with *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10* and supports 53 interrupt sources with 7 priority levels.

The FU540-C000 PLIC resides in the `t1C1k` timing domain, allowing for relaxed timing requirements. The latency of global interrupts, as perceived by a hart, increases with the ratio of the `coreC1k` frequency and the `t1C1k` frequency.

10.1 Memory Map

The memory map for the FU540-C000 PLIC control registers is shown in Table 37. The PLIC memory map has been designed to only require naturally aligned 32-bit memory accesses.

PLIC Register Map

10.2 Interrupt Sources

The FU540-C000 has 53 interrupt sources. These are driven by various on-chip devices as listed in Table 38. These signals are positive-level triggered.

In the PLIC, as specified in *The RISC-V Instruction Set Manual, Volume II: Privileged Architecture, Version 1.10*, Global Interrupt ID 0 is defined to mean "no interrupt."

Source Start	Source End	Source
1	3	L2 Cache
4	4	UART0
5	5	UART1
6	6	QSPI2
7	22	GPIO
23	30	DMA
31	31	DDR Subsystem
32	41	Chiplink MSI
42	45	PWM0
46	49	PWM1
50	50	I2C
51	51	QSPI0
52	52	QSPI1
53	53	Gigabit Ethernet

Table 38: PLIC Interrupt Source Mapping

10.3 Interrupt Priorities

Each PLIC interrupt source can be assigned a priority by writing to its 32-bit memory-mapped priority register. The FU540-C000 supports 7 levels of priority. A priority value of 0 is reserved to mean "never interrupt" and effectively disables the interrupt. Priority 1 is the lowest active priority, and priority 7 is the highest. Ties between global interrupts of the same priority are broken by the Interrupt ID; interrupts with the lowest ID have the highest effective priority. See Table 39 for the detailed register description.

PLIC Interrupt Priority Register (priority)				
Base Address		0x0C00_0000 + 4 × Interrupt ID		
Bits	Field Name	Attr.	Rst.	Description
[2:0]	Priority	RW	X	Sets the priority for a given global interrupt.
[31:3]	Reserved	RO	0	

Table 39: PLIC Interrupt Priority Registers

10.4 Interrupt Pending Bits

The current status of the interrupt source pending bits in the PLIC core can be read from the pending array, organized as 2 words of 32 bits. The pending bit for interrupt ID N is stored in bit $(N \bmod 32)$ of word $(N/32)$. As such, the FU540-C000 has 2 interrupt pending registers. Bit 0 of word 0, which represents the non-existent interrupt source 0, is hardwired to zero.

A pending bit in the PLIC core can be cleared by setting the associated enable bit then performing a claim as described in Section 10.7.

PLIC Interrupt Pending Register 1 (pending1)				
Base Address		0x0C00_1000		
Bits	Field Name	Attr.	Rst.	Description
0	Interrupt 0 Pending	RO	0	Non-existent global interrupt 0 is hardwired to zero
1	Interrupt 1 Pending	RO	0	Pending bit for global interrupt 1
2	Interrupt 2 Pending	RO	0	Pending bit for global interrupt 2
...				
31	Interrupt 31 Pending	RO	0	Pending bit for global interrupt 31

Table 40: PLIC Interrupt Pending Register 1

PLIC Interrupt Pending Register 2 (pending2)				
Base Address		0x0C00_1004		
Bits	Field Name	Attr.	Rst.	Description
0	Interrupt 32 Pending	RO	0	Pending bit for global interrupt 32
...				
21	Interrupt 53 Pending	RO	0	Pending bit for global interrupt 53
[31:22]	Reserved	WIRI	X	

Table 41: PLIC Interrupt Pending Register 2

10.5 Interrupt Enables

Each global interrupt can be enabled by setting the corresponding bit in the enables registers. The enables registers are accessed as a contiguous array of 2×32 -bit words, packed the same way as the pending bits. Bit 0 of enable word 0 represents the non-existent interrupt ID 0 and is hardwired to 0.

64-bit and 32-bit word accesses are supported by the enables array in SiFive RV64 systems.

PLIC Interrupt Enable Register 1 (enable1) for Hart 0 M-Mode				
Base Address		0x0C00_2000		
Bits	Field Name	Attr.	Rst.	Description
0	Interrupt 0 Enable	RO	0	Non-existent global interrupt 0 is hard-wired to zero
1	Interrupt 1 Enable	RW	X	Enable bit for global interrupt 1
2	Interrupt 2 Enable	RW	X	Enable bit for global interrupt 2
...				
31	Interrupt 31 Enable	RW	X	Enable bit for global interrupt 31

Table 42: PLIC Interrupt Enable Register 1 for Hart 0 M-Mode

PLIC Interrupt Enable Register 2 (enable2) for Hart 4 S-Mode				
Base Address		0x0C00_2404		
Bits	Field Name	Attr.	Rst.	Description
0	Interrupt 32 Enable	RW	X	Enable bit for global interrupt 32
...				
21	Interrupt 53 Enable	RW	X	Enable bit for global interrupt 53
[31:22]	Reserved	RO	0	

Table 43: PLIC Interrupt Enable Register 2 for Hart 4 S-Mode

10.6 Priority Thresholds

The FU540-C000 supports setting of an interrupt priority threshold via the threshold register. The threshold is a **WARL** field, where the FU540-C000 supports a maximum threshold of 7.

The FU540-C000 masks all PLIC interrupts of a priority less than or equal to threshold. For example, a threshold value of zero permits all interrupts with non-zero priority, whereas a value of 7 masks all interrupts.

PLIC Interrupt Priority Threshold Register (threshold)				
Base Address		0x0C20_0000		
[2:0]	Threshold	RW	X	Sets the priority threshold
[31:3]	Reserved	RO	0	

Table 44: PLIC Interrupt Threshold Register

10.7 Interrupt Claim Process

A FU540-C000 hart can perform an interrupt claim by reading the `claim/complete` register (Table 45), which returns the ID of the highest-priority pending interrupt or zero if there is no pending interrupt. A successful claim also atomically clears the corresponding pending bit on the interrupt source.

A FU540-C000 hart can perform a claim at any time, even if the MEIP bit in its `mip` (Table 22) register is not set.

The claim operation is not affected by the setting of the priority threshold register.

10.8 Interrupt Completion

A FU540-C000 hart signals it has completed executing an interrupt handler by writing the interrupt ID it received from the claim to the `claim/complete` register (Table 45). The PLIC does not check whether the completion ID is the same as the last claim ID for that target. If the completion ID does not match an interrupt source that is currently enabled for the target, the completion is silently ignored.

PLIC Claim/Complete Register (claim)				
Base Address		0x0C20_0004		
[31:0]	Interrupt Claim/ Complete for Hart 0 M-Mode	RW	X	A read of zero indicates that no inter- rupts are pending. A non-zero read contains the id of the highest pending interrupt. A write to this register signals completion of the interrupt id written.

Table 45: PLIC Interrupt Claim/Complete Register for Hart 0 M-Mode

Chapter 11

Level 2 Cache Controller

This chapter describes the functionality of the Level 2 Cache Controller used in the FU540-C000.

11.1 Level 2 Cache Controller Overview

The SiFive Level 2 Cache Controller is used to provide access to fast copies of memory for masters in a Core Complex. The Level 2 Cache Controller also acts as directory-based coherency manager.

The SiFive Level 2 Cache Controller offers extensive flexibility as it allows for several features in addition to the Level 2 Cache functionality. These include memory-mapped access to L2 Cache RAM for disabled cache ways, scratchpad functionality, way masking and locking, ECC support with error tracking statistics, error injection, and interrupt signaling capabilities.

These features are described in Section 11.2.

11.2 Functional Description

The FU540-C000 L2 Cache Controller is configured into 4 banks. Each bank contains 512 sets of 16 ways and each way contains a 64-byte block. This subdivision into banks helps facilitate increased available bandwidth between CPU masters and the L2 Cache as each bank has its own 128-bit TL-C inner port. As such, multiple requests to different banks may proceed in parallel.

The outer port of the L2 Cache Controller is a 256-bit TL-C port shared among all banks and typically connected to a DDR controller. The overall organization of the L2 Cache Controller is depicted in Figure 4.

Figure 4: Organization of the SiFive L2 Cache Controller

11.2.1 Way Enable and the L2 Loosely Integrated Memory (L2-LIM)

Similar to the ITIM discussed in Chapter 3, the SiFive Level 2 Cache Controller allows for its SRAMs to act either as direct addressed memory in the Core Complex address space or as a cache that is controlled by the L2 Cache Controller and which can contain a copy of any cacheable address.

When cache ways are disabled, they are addressable in the L2 Loosely Integrated Memory (L2-LIM) address space as described in the FU540-C000 memory map in Chapter 5. Fetching instructions or data from the L2-LIM provides deterministic behavior equivalent to an L2 cache hit, with no possibility of a cache miss. Accesses to L2-LIM are always given priority over cache way accesses, which target the same L2 cache bank.

Out of reset, all ways, except for way 0, are disabled. Cache ways can be enabled by writing to the `wayEnable` register described in Section 11.4.2. Once a cache way is enabled, it can not be disabled unless the FU540-C000 is reset. The highest numbered L2 Cache Way is mapped to

the lowest L2-LIM address space, and way 1 occupies the highest L2-LIM address range. As L2 cache ways are enabled, the size of the L2-LIM address space shrinks. The mapping of L2 cache ways to L2-LIM address space is shown in Figure 5.

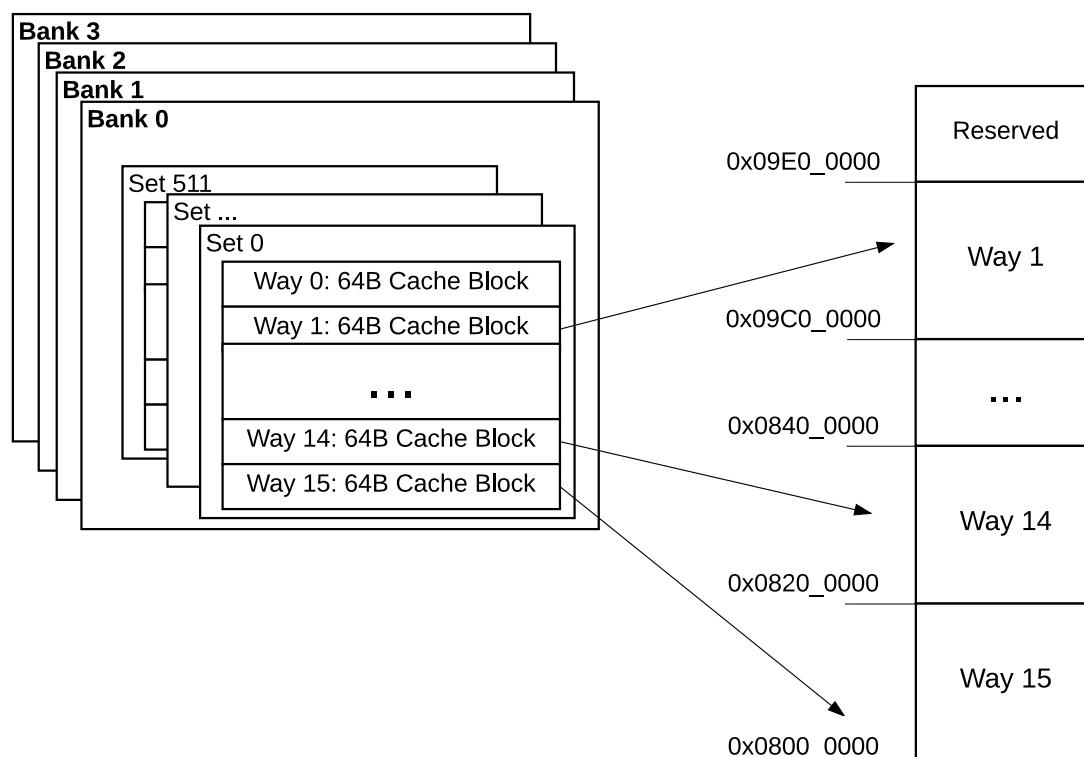

Figure 5: Mapping of L2 Cache Ways to L2-LIM Addresses

11.2.2 Way Masking and Locking

The SiFive L2 Cache Controller can control the amount of cache memory a CPU master is able to allocate into by using the wayMaskX register described in Section 11.4.11. Note that wayMaskX registers only affect allocations, and reads can still occur to ways that are masked. As such, it becomes possible to lock down specific cache ways by masking them in all wayMaskX registers. In this scenario, all masters can still read data in the locked cache ways but cannot evict data.

11.2.3 L2 Scratchpad

The SiFive L2 Cache Controller has a dedicated scratchpad address region that allows for allocation into the cache using an address range which is not memory backed. This address region is denoted as the L2 Zero Device in the Memory Map in Chapter 5. Writes to the scratchpad region allocate into cache ways that are enabled and not masked. Care must be taken with the scratchpad, however, as there is no memory backing this address space. Cache evictions from addresses in the scratchpad result in data loss.

The main advantage of the L2 Scratchpad over the L2-LIM is that it is a cacheable region allowing for data stored to the scratchpad to also be cached in a master's L1 data cache resulting in faster access.

The recommended procedure for using the L2 Scratchpad is as follows:

1. Use the `WayEnable` register to enable the desired cache ways.
2. Designate a single master that will allocate into the scratchpad. For this procedure, we designate this master as Master S. All other masters are denoted as Masters X.
3. Masters X: Write to the `wayMaskX` register to mask the ways that are to be used for the scratchpad. This prevents Masters X from evicting cache lines in the designated scratchpad ways.
4. Master S: Write to the `wayMaskX` register to mask all ways *except* the ways that are to be used for the scratchpad. At this point, Master S should only be able to allocate into the cache ways meant to be used as a scratchpad.
5. Master S: Write scratchpad data into the L2 Scratchpad address range (L2 Zero Device).
6. Master S: Use the `wayMaskX` register to mask the scratchpad ways for Master S so that it is no longer able to evict cache lines from the designated scratchpad ways.
7. At this point, the scratchpad ways should contain the scratchpad data, with all masters able to read, write, and execute from this address space, and no masters able to evict the scratchpad contents.

11.2.4 Error Correcting Codes (ECC)

The SiFive Level 2 Cache Controller supports ECC. ECC is applied to both categories of SRAM used, the data SRAMs and the meta-data SRAMs (index, tag, and directory information). The data SRAMs use Single Error Correction and Double Error Detection (SECCDED). The meta-data SRAMs use Single Error Correction (SEC).

Whenever a correctable error is detected, the cache immediately repairs the corrupted bit and writes it back to SRAM. This corrective procedure is completely invisible to application software. However, to support diagnostics, the cache records the address of the most recently corrected meta-data and data errors. Whenever a new error is corrected, a counter is increased and an interrupt is raised. There are independent addresses, counters, and interrupts for correctable meta-data and data errors.

`DirError`, `DataError`, and `DataFail` signals are used to indicate that an L2 meta-data, data, or uncorrectable L2 data error has occurred, respectively. These signals are connected to the PLIC as described in Chapter 10 and are cleared upon reading their respective count registers.

11.3 Memory Map

The L2 Cache Controller memory map is shown in Table 46.

Offset	Name	Description
0x000	Config	Information about the Cache Configuration
0x008	WayEnable	The index of the largest way which has been enabled. May only be increased.
0x040	ECCInjectError	Inject an ECC Error
0x100	DirECCFixLow	The low 32-bits of the most recent address to fail ECC
0x104	DirECCFixHigh	The high 32-bits of the most recent address to fail ECC
0x108	DirECCFixCount	Reports the number of times an ECC error occurred
0x140	DatECCFixLow	The low 32-bits of the most recent address to fail ECC
0x144	DatECCFixHigh	The high 32-bits of the most recent address to fail ECC
0x148	DatECCFixCount	Reports the number of times an ECC error occurred
0x160	DatECCFailLow	The low 32-bits of the most recent address to fail ECC
0x164	DatECCFailHigh	The high 32-bits of the most recent address to fail ECC
0x168	DatECCFailCount	Reports the number of times an ECC error occurred
0x200	Flush64	Flush the physical address equal to the 64-bit written data from the cache
0x240	Flush32	Flush the physical address equal to the 32-bit written data << 4 from the cache
0x800	WayMask0	Master 0 way mask register
0x808	WayMask1	Master 1 way mask register
0x810	WayMask2	Master 2 way mask register
0x818	WayMask3	Master 3 way mask register
0x820	WayMask4	Master 4 way mask register
0x828	WayMask5	Master 5 way mask register
0x830	WayMask6	Master 6 way mask register
0x838	WayMask7	Master 7 way mask register
0x840	WayMask8	Master 8 way mask register
0x848	WayMask9	Master 9 way mask register
0x850	WayMask10	Master 10 way mask register
0x858	WayMask11	Master 11 way mask register
0x860	WayMask12	Master 12 way mask register
0x868	WayMask13	Master 13 way mask register
0x870	WayMask14	Master 14 way mask register
0x878	WayMask15	Master 15 way mask register
0x880	WayMask16	Master 16 way mask register
0x888	WayMask17	Master 17 way mask register
0x890	WayMask18	Master 18 way mask register
0x898	WayMask19	Master 19 way mask register
0x8A0	WayMask20	Master 20 way mask register

Table 46: Register offsets within the L2 Cache Controller Control Memory Map

11.4 Register Descriptions

This section describes the functionality of the memory-mapped registers in the Level 2 Cache Controller.

11.4.1 Cache Configuration Register (Config)

The Config Register can be used to programmatically determine information regarding the cache size and organization.

Config: Information about the Cache Configuration (Config)				
Register Offset		0x0		
Bits	Field Name	Attr.	Rst.	Description
[7:0]	Banks	R0	0x4	Number of banks in the cache
[15:8]	Ways	R0	0x10	Number of ways per bank
[23:16]	lgSets	R0	0x9	Base-2 logarithm of the sets per bank
[31:24]	lgBlockBytes	R0	0x6	Base-2 logarithm of the bytes per cache block

Table 47: Config: Information about the Cache Configuration

11.4.2 Way Enable Register (wayEnable)

The wayEnable register determines which ways of the Level 2 Cache Controller are enabled as cache. Cache ways that are not enabled are mapped into the FU540-C000's L2-LIM (Loosely Integrated Memory) as described in the memory map in Chapter 5.

This register is initialized to 0 on reset and may only be increased. This means that, out of reset, only a single L2 cache way is enabled, as one cache way must always remain enabled. Once a cache way is enabled, the only way to map it back into the L2-LIM address space is by a reset.

WayEnable: The index of the largest way which has been enabled. May only be increased. (WayEnable)				
Register Offset		0x8		
Bits	Field Name	Attr.	Rst.	Description
[7:0]	WayEnable	RW	0x0	The index of the largest way which has been enabled. May only be increased.
[31:8]	Reserved			

Table 48: WayEnable: The index of the largest way which has been enabled. May only be increased.

11.4.3 ECC Error Injection Register (ECCInjectError)

The ECCInjectError register can be used to insert an ECC error into either the backing data or meta-data SRAM. This function can be used to test error correction logic, measurement, and recovery.

ECCInjectError: Inject an ECC Error (ECCInjectError)				
Register Offset		0x40		
Bits	Field Name	Attr.	Rst.	Description
[7:0]	ECCToggleBit	RW	0x0	Toggle (corrupt) this bit index on the next cache operation
[15:8]	Reserved			
16	ECCToggleType	RW	0x0	Toggle (corrupt) a bit in 0=data or 1=directory
[31:17]	Reserved			

Table 49: ECCInjectError: Inject an ECC Error**11.4.4 ECC Directory Fix Address (DirECCFix*)**

The DirECCFixHi and DirECCFixLow registers are read-only registers that contain the address of the most recently corrected meta-data error. This field supplies only the portions of the address that correspond to the affected set and bank, since all ways are corrected together.

11.4.5 ECC Directory Fix Count (DirECCFixCount)

The DirECCFixCount register is a read-only register that contains the number of corrected L2 meta-data errors.

Reading this register clears the DirError interrupt signal described in Section 11.2.4.

11.4.6 ECC Data Fix Address (DatECCFix*)

The DatECCFixLow and DatECCFixHigh registers are read-only registers that contain the address of the most recently corrected L2 data error.

11.4.7 ECC Data Fix Count (DatECCFixCount)

The DataECCFixCount register is a read-only register that contains the number of corrected data errors.

Reading this register clears the DataError interrupt signal described in Section 11.2.4.

11.4.8 ECC Data Fail Address (DatECCFail*)

The DatECCFailLow and DatECCFailHigh registers are a read-only registers that contain the address of the most recent uncorrected L2 data error.

11.4.9 ECC Data Fail Count (DatECCFailCount)

The DatECCFailCount register is a read-only register that contains the number of uncorrected data errors.

Reading this register clears the DataFail interrupt signal described in Section 11.2.4.

11.4.10 Cache Flush Registers (Flush*)

The FU540-C000 L2 Cache Controller provides two registers that can be used for flushing specific cache blocks.

Flush64 is a 64-bit write-only register that flushes the cache block containing the address written. Flush32 is a 32-bit write-only register that flushes a cache block containing the written address left shifted by 4 bytes. In both registers, all bits must be written in a single access for the flush to take effect.

11.4.11 Way Mask Registers (wayMask*)

The wayMaskX register allows a master connected to the L2 Cache Controller to specify which L2 cache ways can be evicted by master X. Masters can still access memory cached in masked ways. The mapping between masters and their L2 master IDs is shown in Table 52.

At least one cache way must be enabled. It is recommended to set/clear bits in this register using atomic operations.

WayMask0: Master 0 way mask register (wayMask0)				
Register Offset		0x800		
Bits	Field Name	Attr.	Rst.	Description
0	WayMask0[0]	RW	0x1	Enable way 0 for Master 0
1	WayMask0[1]	RW	0x1	Enable way 1 for Master 0
2	WayMask0[2]	RW	0x1	Enable way 2 for Master 0
3	WayMask0[3]	RW	0x1	Enable way 3 for Master 0
4	WayMask0[4]	RW	0x1	Enable way 4 for Master 0
5	WayMask0[5]	RW	0x1	Enable way 5 for Master 0
6	WayMask0[6]	RW	0x1	Enable way 6 for Master 0
7	WayMask0[7]	RW	0x1	Enable way 7 for Master 0
8	WayMask0[8]	RW	0x1	Enable way 8 for Master 0
9	WayMask0[9]	RW	0x1	Enable way 9 for Master 0
10	WayMask0[10]	RW	0x1	Enable way 10 for Master 0
11	WayMask0[11]	RW	0x1	Enable way 11 for Master 0
12	WayMask0[12]	RW	0x1	Enable way 12 for Master 0
13	WayMask0[13]	RW	0x1	Enable way 13 for Master 0
14	WayMask0[14]	RW	0x1	Enable way 14 for Master 0
15	WayMask0[15]	RW	0x1	Enable way 15 for Master 0
[63:16]	Reserved

Chapter 12

Platform DMA Engine (PDMA)

This chapter describes the SiFive platform DMA (PDMA) engine. The PDMA unit has memory-mapped control registers accessed over a TileLink slave interface to allow software to set up DMA transfers. It also has a TileLink bus master port into the TileLink bus fabric to allow it to autonomously transfer data between slave devices and main memory or to rapidly copy data between two locations in memory. The PDMA unit can support multiple independent simultaneous DMA transfers using different PDMA channels and can generate PLIC interrupts on various conditions during DMA execution.

12.1 Functional Description

12.1.1 PDMA Channels

The FU540-C000 PDMA has 4 independent DMA channels, which operate concurrently to support multiple simultaneous transfers. Each channel has an independent set of control registers, which are described in Section 12.2 and Section 12.3, and 8 interrupts described in Section 12.1.2.

12.1.2 Interrupts

The PDMA has 8 interrupts per channel that are used to signal when either a transfer has completed, or when a transfer error has occurred.

A channel's interrupts are configured using its `control` register described in Section 12.3.1. The mapping of the FU540-C000 PDMA interrupt signals to the PLIC are described in Chapter 10.

Interrupt	Purpose
0	Channel 0 transfer complete
1	Channel 0 transfer encountered an error
2	Channel 1 transfer complete
3	Channel 1 transfer encountered an error
4	Channel 2 transfer complete
5	Channel 2 transfer encountered an error
6	Channel 3 transfer complete
7	Channel 3 transfer encountered an error

Table 53: DMA interrupt map

12.2 PDMA Memory Map

The PDMA has an independent set of registers for each channel. Each channel's registers are offset by 0x1000 so that the base address for a given PDMA channel is as follows:

$$\text{PDMA Base Address} + (0x1000 \times \text{Channel ID}).$$

Table 54 shows the memory map of the PDMA control registers.

Platform DMA Memory Map (single channel)				
Channel Base Address		PDMA Base Address + (0x1000 × Channel ID)		
Offset	Width	Attr.	Description	Notes
0x000	4B	RW	Control	Channel Control Register
0x004	4B	RW	NextConfig	Next transfer type
0x008	8B	RW	NextBytes	Number of bytes to move
0x010	8B	RW	NextDestination	Destination start address
0x018	8B	RW	NextSource	Source start address
0x104	4B	RO	ExecConfig	Active transfer type
0x108	8B	RO	ExecBytes	Number of bytes remaining
0x110	8B	RO	ExecDestination	Destination current address
0x118	8B	RO	ExecSource	Source current address

Table 54: Platform DMA Memory Map

12.3 Register Descriptions

This section describes the functionality of the memory-mapped registers in the Platform DMA Engine.

12.3.1 Channel Control Register (Control)

The Control register holds the current status of the channel. It can be used to claim a PDMA channel, initiate a transfer, enable interrupts, and check if a transfer has completed.

Channel Control Register (Control)				
Register Offset		0x000 + (0x1000 × Channel ID)		
Bits	Field Name	Attr.	Rst.	Notes
0	claim	RW	0x0	Indicates that the channel is in use. Setting this clears all of the channel's Next registers. This bit can only be cleared when run is low.
1	run	RW	0x0	Setting this bit starts a DMA transfer by copying the Next registers into their Exec counterparts.
[25:2]	Reserved			
26	doneIE	RW	0x0	Setting this bit will trigger the channel's Done interrupt once a transfer is complete.
27	errorIE	RW	0x0	Setting this bit will trigger the channel's Error interrupt upon receiving a bus error.
[29:28]	Reserved			
30	done	RW	0x0	Indicates that a transfer has completed since the channel was claimed.
31	error	RW	0x0	Indicates that a transfer error has occurred since the channel was claimed.

Table 55: Channel Control Register

12.3.2 Channel Next Configuration Register (NextConfig)

The read-write NextConfig register holds the transfer request type. The wsize and rsize fields are used to determine the size and alignment of individual PDMA transactions, as a single PDMA transfer might require multiple transactions. There is an upper-bound of 64 bytes on a transaction size. These fields are WARL, so the actual size used can be determined by reading the field after writing the requested size.

The PDMA can be programmed to automatically repeat a transfer by setting the repeat bit field. If this bit is set, once the transfer completes, the Next registers are automatically copied to the Exec registers and a new transfer is initiated. The Control.run bit remains set during “repeated” transactions. To stop repeating transfers, a master can monitor the channel's Done interrupt and lower the repeat bit accordingly.

Channel Next Configuration Register (NextConfig)				
Register Offset		0x004 + (0x1000 × Channel ID)		
Bits	Field Name	Attr.	Rst.	Notes
[1:0]	Reserved			
2	repeat	RW	0x0	If set, the Exec registers are reloaded from the Next registers once a transfer is complete. The repeat bit must be cleared by software for the sequence to stop.
3	order	RW	0x0	Enforces strict ordering by only allowing one of each transfer type in-flight at a time
[25:4]	Reserved			
[27:24]	wsiz	WARL	0x0	Base 2 Logarithm of PDMA transaction sizes; e.g. 0 is 1 byte, 3 is 8 bytes, 5 is 32 bytes
[31:28]	rsiz	WARL	0x0	Base 2 Logarithm of PDMA transaction sizes; e.g. 0 is 1 byte, 3 is 8 bytes, 5 is 32 bytes

Table 56: Channel Next Configuration Register

12.3.3 Channel Byte Transfer Register (NextBytes)

The read-write NextBytes register holds the number of bytes to be transferred by the channel. The NextConfig.xsiz fields are used to determine the size of the individual transactions that will be used to transfer the number of bytes specified in this register.

The NextBytes register is a WARL register with a maximum count that can be much smaller than the physical address size of the machine.

12.3.4 Channel Destination Register (NextDestination)

The read-write NextDestination register holds the physical address of the destination for the transfer.

12.3.5 Channel Source Address (NextSource)

The read-write NextSource register holds the physical address of the source data for the transfer.

12.3.6 Channel Exec Registers (Exec*)

Each PDMA channel has a set of Exec registers which provide information on the transfer that is currently executing. These registers are read-only and initialized when Control.run is set. Upon initialization, the Next registers are copied into the Exec registers and a transfer begins.

The status of the transfer can be monitored by reading the Exec registers. ExecBytes indicates the number of bytes remaining in a transfer, ExecSource indicates the current source address, and ExecDestination indicates the current destination address.

Chapter 13

Universal Asynchronous Receiver/Transmitter (UART)

This chapter describes the operation of the SiFive Universal Asynchronous Receiver/Transmitter (UART).

13.1 UART Overview

The UART peripheral supports the following features:

- 8-N-1 and 8-N-2 formats: 8 data bits, no parity bit, 1 start bit, 1 or 2 stop bits
- 8-entry transmit and receive FIFO buffers with programmable watermark interrupts
- 16× Rx oversampling with 2/3 majority voting per bit

The UART peripheral does not support hardware flow control or other modem control signals, or synchronous serial data transfers.

13.2 UART Instances in FU540-C000

FU540-C000 contains two UART instances. Their addresses and parameters are shown in Table 57.

Instance Number	Address	div_width	div_init	TX FIFO Depth	RX FIFO Depth
0	0x10010000	20	289	8	8
1	0x10011000	20	289	8	8

Table 57: UART Instances

13.3 Memory Map

The memory map for the UART control registers is shown in Table 58. The UART memory map has been designed to require only naturally aligned 32-bit memory accesses.

Offset	Name	Description
0x00	txdata	Transmit data register
0x04	rxdata	Receive data register
0x08	txctrl	Transmit control register
0x0C	rxctrl	Receive control register
0x10	ie	UART interrupt enable
0x14	ip	UART interrupt pending
0x18	div	Baud rate divisor

Table 58: Register offsets within UART memory map

13.4 Transmit Data Register (txdata)

Writing to the txdata register enqueues the character contained in the data field to the transmit FIFO if the FIFO is able to accept new entries. Reading from txdata returns the current value of the full flag and zero in the data field. The full flag indicates whether the transmit FIFO is able to accept new entries; when set, writes to data are ignored. A RISC-V amoswap instruction can be used to both read the full status and attempt to enqueue data, with a non-zero return value indicating the character was not accepted.

Transmit Data Register (txdata)				
Register Offset		0x0		
Bits	Field Name	Attr.	Rst.	Description
[7:0]	data	RW	X	Transmit data
[30:8]	Reserved			
31	full	RW	X	Transmit FIFO full

Table 59: Transmit Data Register

13.5 Receive Data Register (rxdata)

Reading the rxdata register dequeues a character from the receive FIFO and returns the value in the data field. The empty flag indicates if the receive FIFO was empty; when set, the data field does not contain a valid character. Writes to rxdata are ignored.

Receive Data Register (rxdata)				
Register Offset		0x4		
Bits	Field Name	Attr.	Rst.	Description
[7:0]	data	R0	X	Received data
[30:8]	Reserved			
31	empty	R0	X	Receive FIFO empty

Table 60: Receive Data Register

13.6 Transmit Control Register (txctr1)

The read-write txctr1 register controls the operation of the transmit channel. The txen bit controls whether the Tx channel is active. When cleared, transmission of Tx FIFO contents is suppressed, and the txd pin is driven high.

The nstop field specifies the number of stop bits: 0 for one stop bit and 1 for two stop bits.

The txcnt field specifies the threshold at which the Tx FIFO watermark interrupt triggers.

The txctr1 register is reset to 0.

Transmit Control Register (txctr1)				
Register Offset		0x8		
Bits	Field Name	Attr.	Rst.	Description
0	txen	RW	0x0	Transmit enable
1	nstop	RW	0x0	Number of stop bits
[15:2]	Reserved			
[18:16]	txcnt	RW	0x0	Transmit watermark level
[31:19]	Reserved			

Table 61: Transmit Control Register

13.7 Receive Control Register (rxctr1)

The read-write rxctr1 register controls the operation of the receive channel. The rxen bit controls whether the Rx channel is active. When cleared, the state of the rxd pin is ignored, and no characters will be enqueued into the Rx FIFO.

The rxcnt field specifies the threshold at which the Rx FIFO watermark interrupt triggers.

The rxctr1 register is reset to 0. Characters are enqueued when a zero (low) start bit is seen.

Receive Control Register (rxctr1)				
Register Offset		0xC		
Bits	Field Name	Attr.	Rst.	Description
0	rxen	RW	0x0	Receive enable
[15:1]	Reserved			
[18:16]	rxcnt	RW	0x0	Receive watermark level
[31:19]	Reserved			

Table 62: Receive Control Register

13.8 Interrupt Registers (ip and ie)

The ip register is a read-only register indicating the pending interrupt conditions, and the read-write ie register controls which UART interrupts are enabled. ie is reset to 0.

The txwm condition becomes raised when the number of entries in the transmit FIFO is strictly less than the count specified by the txcnt field of the txctr1 register. The pending bit is cleared when sufficient entries have been enqueued to exceed the watermark.

The rxwm condition becomes raised when the number of entries in the receive FIFO is strictly greater than the count specified by the rxcnt field of the rxctr1 register. The pending bit is cleared when sufficient entries have been dequeued to fall below the watermark.

UART Interrupt Enable Register (ie)				
Register Offset		0x10		
Bits	Field Name	Attr.	Rst.	Description
0	txwm	RW	0x0	Transmit watermark interrupt enable
1	rxwm	RW	0x0	Receive watermark interrupt enable
[31:2]	Reserved			

Table 63: UART Interrupt Enable Register

UART Interrupt Pending Register (ip)				
Register Offset		0x14		
Bits	Field Name	Attr.	Rst.	Description
0	txwm	RO	X	Transmit watermark interrupt pending
1	rxwm	RO	X	Receive watermark interrupt pending
[31:2]	Reserved			

Table 64: UART Interrupt Pending Register

13.9 Baud Rate Divisor Register (div)

The read-write, div_width-bit div register specifies the divisor used by baud rate generation for both Tx and Rx channels. The relationship between the input clock and baud rate is given by the following formula:

$$f_{\text{baud}} = \frac{f_{\text{in}}}{\text{div} + 1}$$

The input clock is the bus clock `tlclk`. The reset value of the register is set to `div_init`, which is tuned to provide a 115200 baud output out of reset given the expected frequency of `tlclk`.

Table 65 shows divisors for some common core clock rates and commonly used baud rates. Note that the table shows the divide ratios, which are one greater than the value stored in the `div` register.

tlclk (MHz)	Target Baud (Hz)	Divisor	Actual Baud (Hz)	Error (%)
500	31250	16000	31250	0
500	115200	4340	115207	0.0064
500	250000	2000	250000	0
500	1843200	271	1845018	0.099
750	31250	24000	31250	0
750	115200	6510	115207	0.0064
750	250000	3000	250000	0
750	1843200	407	1842751	0.024

Table 65: Common baud rates (MIDI=31250, DMX=250000) and required divide values to achieve them with given bus clock frequencies. The divide values are one greater than the value stored in the `div` register.

The receive channel is sampled at 16× the baud rate, and a majority vote over 3 neighboring bits is used to determine the received value. For this reason, the divisor must be ≥16 for a receive channel.

Baud Rate Divisor Register (div)				
Register Offset		0x18		
Bits	Field Name	Attr.	Rst.	Description
[15:0]	div	RW	X	Baud rate divisor. <code>div_width</code> bits wide, and the reset value is <code>div_init</code> .
[31:16]	Reserved			

Table 66: Baud Rate Divisor Register

Chapter 14

Pulse Width Modulator (PWM)

This chapter describes the operation of the Pulse-Width Modulation peripheral (PWM).

14.1 PWM Overview

Figure 6 shows an overview of the PWM peripheral. The default configuration described here has four independent PWM comparators (pwmcmp0–pwmcmp3), but each PWM Peripheral is parameterized by the number of comparators it has (ncmp). The PWM block can generate multiple types of waveforms on output pins (pwmXgpio) and can also be used to generate several forms of internal timer interrupt. The comparator results are captured in the pwmcmpXip flops and then fed to the PLIC as potential interrupt sources. The pwmcmpXip outputs are further processed by an output ganging stage before being fed to the GPIOs.

PWM instances can support comparator precisions (cmpwidth) up to 16 bits, with the example described here having the full 16 bits. To support clock scaling, the pwmcount register is 15 bits wider than the comparator precision cmpwidth.

Figure 6: PWM Peripheral

14.2 PWM Instances in FU540-C000

FU540-C000 contains two PWM instances. Their addresses and parameters are shown in Table 67.

Instance Number	Address	ncmp	cmpwidth
0	0x10020000	4	16
1	0x10021000	4	16

Table 67: PWM Instances

14.3 PWM Memory Map

The memory map for the PWM peripheral is shown in Table 68.

Offset	Name	Description
0x00	pwmcfg	PWM configuration register
0x04	Reserved	
0x08	pwmcount	PWM count register
0x0C	Reserved	
0x10	pwms	Scaled PWM count register
0x14	Reserved

0x1C	Reserved	
0x20	pwmcmp0	PWM 0 compare register
0x24	pwmcmp1	PWM 1 compare register
0x28	pwmcmp2	PWM 2 compare register
0x2C	pwmcmp3	PWM 3 compare register

Table 68: SiFive PWM memory map, offsets relative to PWM peripheral base address

14.4 PWM Count Register (*pwmcount*)

The PWM unit is based around a counter held in *pwmcount*. The counter can be read or written over the TileLink bus. The *pwmcount* register is $(15 + \text{cmpwidth})$ bits wide. For example, for *cmpwidth* of 16 bits, the counter is held in *pwmcount*[30:0], and bit 31 of *pwmcount* returns a zero when read.

When used for PWM generation, the counter is normally incremented at a fixed rate then reset to zero at the end of every PWM cycle. The PWM counter is either reset when the scaled counter *pwms* reaches the value in *pwmcmp0*, or is simply allowed to wrap around to zero.

The counter can also be used in one-shot mode, where it disables counting after the first reset.

PWM Count Register (<i>pwmcount</i>)				
Register Offset		0x8		
Bits	Field Name	Attr.	Rst.	Description
[30:0]	<i>pwmcount</i>	RW	X	PWM count register. <i>cmpwidth</i> + 15 bits wide.

31	pwm _{cmp3ip}	RW	X	PWM3 Interrupt Pending

Table 70: PWM Configuration Register

The pwm_{cf_g} register contains various control and status information regarding the PWM peripheral, as shown in Table 70.

The pwm_{en}* bits control the conditions under which the PWM counter pwm_{count} is incremented. The counter increments by one each cycle only if any of the enabled conditions are true.

If the pwm_{enalways} bit is set, the PWM counter increments continuously. When pwm_{enoneshot} is set, the counter can increment but pwm_{enoneshot} is reset to zero once the counter resets, disabling further counting (unless pwm_{enalways} is set). The pwm_{enoneshot} bit provides a way for software to generate a single PWM cycle then stop. Software can set the pwm_{enoneshot} again at any time to replay the one-shot waveform. The pwm_{en}* bits are reset at wakeup reset, which disables the PWM counter and saves power.

The 4-bit `pwm-scale` field scales the PWM counter value before feeding it to the PWM comparators. The value in `pwm-scale` is the bit position within the `pwm-count` register of the start of a `cmpwidth`-bit `pwm` field. A value of 0 in `pwm-scale` indicates no scaling, and `pwm` would then be equal to the low `cmpwidth` bits of `pwm-count`. The maximum value of 15 in `pwm-scale` corresponds to dividing the clock rate by 2^{15} , so for an input bus clock of 16 MHz, the LSB of `pwm` will increment at 488.3 Hz.

The `pwm-zero-ctrl` bit, if set, causes the PWM counter `pwm-count` to be automatically reset to zero one cycle after the `pwm` counter value matches the compare value in `pwm-cmp0`. This is normally used to set the period of the PWM cycle. This feature can also be used to implement periodic counter interrupts, where the period is independent of interrupt service time.

14.6 Scaled PWM Count Register (`pwm`)

The Scaled PWM Count Register `pwm` reports the `cmpwidth`-bit portion of `pwm-count` which starts at `pwm-scale`, and is what is used for comparison against the `pwm-cmp` registers.

Scaled PWM Count Register (<code>pwm</code>)				
Register Offset		0x10		
Bits	Field Name	Attr.	Rst.	Description
[15:0]	<code>pwm</code>	RW	X	Scaled PWM count register. <code>cmpwidth</code> bits wide.
[31:16]	Reserved

[15:0]	pwmcmp2	RW	X	PWM 2 Compare Value
[31:16]	Reserved			

Table 74: PWM 2 Compare Register

PWM 3 Compare Register (pwmcmp3)				
Register Offset		0x2C		
Bits	Field Name	Attr.	Rst.	Description
[15:0]	pwmcmp3	RW	X	PWM 3 Compare Value
[31:16]	Reserved			

Table 75: PWM 3 Compare Register

The primary use of the ncmp PWM compare registers is to define the edges of the PWM waveforms within the PWM cycle.

Each compare register is a cmpwidth-bit value against which the current pwms value is compared every cycle. The output of each comparator is high whenever the value of pwms is greater than or equal to the corresponding pwmcmp X .

If the pwmzerocomp bit is set, when pwms reaches or exceeds pwmcmp0, pwmcount is cleared to zero and the current PWM cycle is completed. Otherwise, the counter is allowed to wrap around.

14.8 Deglitch and Sticky Circuitry

To avoid glitches in the PWM waveforms when changing pwmcmp X register values, the pwmdeglitch bit in pwmcfg can be set to capture any high output of a PWM comparator in a sticky bit (pwmcmp X ip for comparator X) and prevent the output falling again within the same PWM cycle. The pwmcmp X ip bits are only allowed to change at the start of the next PWM cycle.

Note

The pwmcmp0ip bit will only be high for one cycle when pwmdeglitch and pwmzerocomp are set where pwmcmp0 is used to define the PWM cycle, but can be used as a regular PWM edge otherwise.

If pwmdeglitch is set, but pwmzerocomp is clear, the deglitch circuit is still operational but is now triggered when pwms contains all 1s and will cause a carry out of the high bit of the pwms incrementer just before the counter wraps to zero.

The `pwmsticky` bit disallows the `pwmcmpXip` registers from clearing if they are already set and is used to ensure interrupts are seen from the `pwmcmpXip` bits.

14.9 Generating Left- or Right-Aligned PWM Waveforms

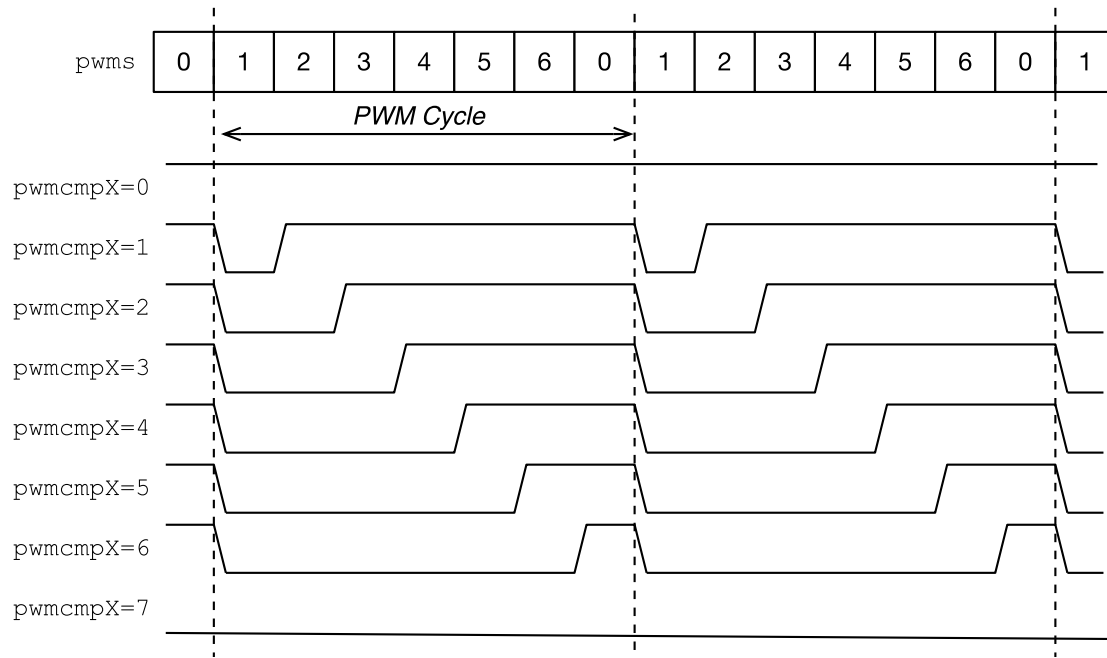

Figure 7: Basic right-aligned PWM waveforms. All possible base waveforms are shown for a 7-clock PWM cycle (`pwmcmp0=6`). The waveforms show the single-cycle delay caused by registering the comparator outputs in the `pwmcmpXip` bits. The signals can be inverted at the GPIOs to generate left-aligned waveforms.

Figure 7 shows the generation of various base PWM waveforms. The figure illustrates that if `pwmcmp0` is set to less than the maximum count value (6 in this case), it is possible to generate both 100% (`pwmcmpX = 0`) and 0% (`pwmcmpX > pwmcmp0`) right-aligned duty cycles using the other comparators. The `pwmcmpXip` bits are routed to the GPIO pads, where they can be optionally and individually inverted, thereby creating left-aligned PWM waveforms (high at beginning of cycle).

14.10 Generating Center-Aligned (Phase-Correct) PWM Waveforms

The simple PWM waveforms in Figure 7 shift the phase of the waveform along with the duty cycle. A per-comparator `pwmcmpXcenter` bit in `pwmcfg` allows a single PWM comparator to generate a center-aligned symmetric duty-cycle as shown in Figure 8. The `pwmcmpXcenter` bit changes the comparator to compare with the bitwise inverted `pwms` value whenever the MSB of `pwms` is high.

This technique provides symmetric PWM waveforms but only when the PWM cycle is at the largest supported size. At a 16 MHz bus clock rate with 16-bit precision, this limits the fastest PWM cycle to 244 Hz, or 62.5 kHz with 8-bit precision. Higher bus clock rates allow proportionally faster PWM cycles using the single comparator center-aligned waveforms. This technique also reduces the effective width resolution by a factor of 2.

pwms	pwmscenter
000	000
001	001
010	010
011	011
100	011
101	010
110	001
111	000

Table 76: Illustration of how count value is inverted before presentation to comparator when `pwmcmpXcenter` is selected, using a 3-bit `pwms` value.

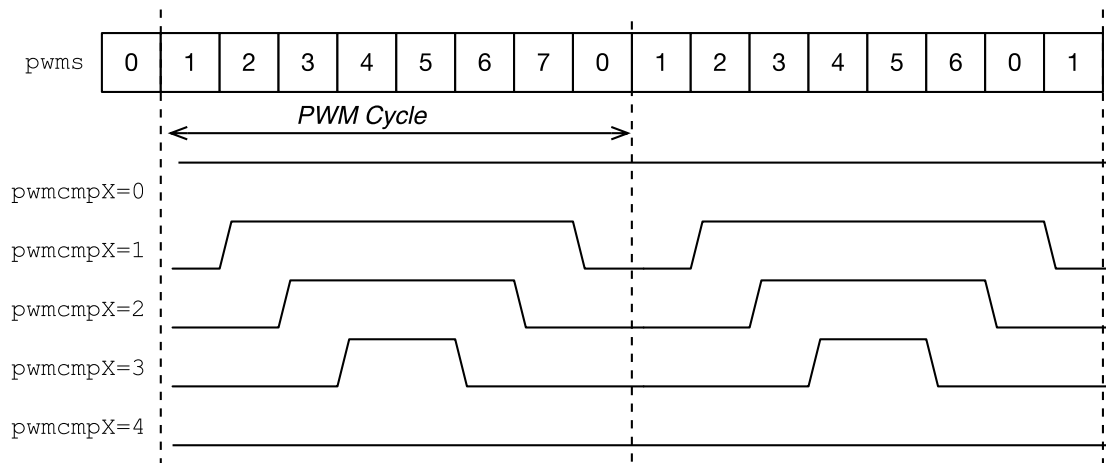

Figure 8: Center-aligned PWM waveforms generated from one comparator. All possible waveforms are shown for a 3-bit PWM precision. The signals can be inverted at the GPIOs to generate opposite-phase waveforms.

When a comparator is operating in center mode, the deglitch circuit allows one 0-to-1 transition during the first half of the cycle and one 1-to-0 transition during the second half of the cycle.

14.11 Generating Arbitrary PWM Waveforms using Ganging

A comparator can be ganged together with its next-highest-numbered neighbor to generate arbitrary PWM pulses. When the `pwmcmpXgang` bit is set, comparator `X` fires and raises its `pwmXgpio` signal. When comparator `X + 1` (or `pwmcmp0` for `pwmcmp3`) fires, the `pwmXgpio` output is reset to zero.

14.12 Generating One-Shot Waveforms

The PWM peripheral can be used to generate precisely timed one-shot pulses by first initializing the other parts of `pwmcfg` then writing a 1 to the `pwmnoneshot` bit. The counter will run for one PWM cycle, then once a reset condition occurs, the `pwmnoneshot` bit is reset in hardware to prevent a second cycle.

14.13 PWM Interrupts

The PWM can be configured to provide periodic counter interrupts by enabling auto-zeroing of the count register when a comparator 0 fires (`pwmzerocmp=1`). The `pwmsticky` bit should also be set to ensure interrupts are not forgotten while waiting to run a handler.

The interrupt pending bits `pwmcmpXip` can be cleared down using writes to the `pwmcfg` register.

The PWM peripheral can also be used as a regular timer with no counter reset (`pwmzerocmp=0`), where the comparators are now used to provide timer interrupts.

Chapter 15

Inter-Integrated Circuit (I²C) Master Interface

The SiFive Inter-Integrated Circuit (I²C) Master Interface is based on OpenCores® I²C Master Core.

Download the original documentation at <https://opencores.org/project,i2c>.

All I²C control register addresses are 4-byte aligned.

15.1 I²C Instance in FU540-C000

FU540-C000 contains one I²C instance. Its address is shown in Table 77.

Instance Number	Address
0	0x10030000

Table 77: I²C Instance

Chapter 16

Serial Peripheral Interface (SPI)

This chapter describes the operation of the SiFive Serial Peripheral Interface (SPI) controller.

16.1 SPI Overview

The SPI controller supports master-only operation over the single-lane, dual-lane, and quad-lane protocols. The baseline controller provides a FIFO-based interface for performing programmed I/O. Software initiates a transfer by enqueueing a frame in the transmit FIFO; when the transfer completes, the slave response is placed in the receive FIFO.

In addition, a SPI controller can implement a SPI flash read sequencer, which exposes the external SPI flash contents as a read/execute-only memory-mapped device. Such controllers are reset to a state that allows memory-mapped reads, under the assumption that the input clock rate is less than 100 MHz and the external SPI flash device supports the common Winbond/Numonyx serial read (0x03) command. Sequential accesses are automatically combined into one long read command for higher performance.

The `fctr1` register controls switching between the memory-mapped and programmed-I/O modes, if applicable. While in programmed-I/O mode, memory-mapped reads do not access the external SPI flash device and instead return 0 immediately. Hardware interlocks ensure that the current transfer completes before mode transitions and control register updates take effect.

16.2 SPI Instances in FU540-C000

FU540-C000 contains three SPI instances. Their addresses and parameters are shown in Table 78.

Instance Number	Flash Controller	Address	cs_width	div_width
QSPI0	Y	0x10040000	1	16
QSPI1	Y	0x10140000	4	16
QSPI2	N	0x10050000	1	16

Table 78: SPI Instances

16.3 Memory Map

The memory map for the SPI control registers is shown in Table 79. The SPI memory map has been designed to require only naturally-aligned 32-bit memory accesses.

Offset	Name	Description
0x00	sckdiv	Serial clock divisor
0x04	sckmode	Serial clock mode
0x08	Reserved	
0x0C	Reserved	
0x10	csid	Chip select ID
0x14	csdef	Chip select default
0x18	csmode	Chip select mode
0x1C	Reserved	
0x20	Reserved	
0x24	Reserved	
0x28	delay0	Delay control 0
0x2C	delay1	Delay control 1
0x30	Reserved	
0x34	Reserved	
0x38	Reserved	
0x3C	Reserved	
0x40	fmt	Frame format
0x44	Reserved	
0x48	txdata	Tx FIFO Data
0x4C	rxdata	Rx FIFO data
0x50	txmark	Tx FIFO watermark
0x54	rxmark	Rx FIFO watermark
0x58	Reserved	
0x5C	Reserved	
0x60	fctrl	SPI flash interface control*
0x64	ffmt	SPI flash instruction format*
0x68	Reserved	
0x6C	Reserved	
0x70	ie	SPI interrupt enable
0x74	ip	SPI interrupt pending

Table 79: Register offsets within the SPI memory map. Registers marked * are present only on controllers with the direct-map flash interface.

16.4 Serial Clock Divisor Register (`sckdiv`)

The `sckdiv` is a `div_width`-bit register that specifies the divisor used for generating the serial clock (SCK). The relationship between the input clock and SCK is given by the following formula:

$$f_{\text{sck}} = \frac{f_{\text{in}}}{2(\text{div} + 1)}$$

The input clock is the bus clock `tlclk`. The reset value of the `div` field is `0x3`.

Serial Clock Divisor Register (<code>sckdiv</code>)				
Register Offset		0x0		
Bits	Field Name	Attr.	Rst.	Description
[11:0]	<code>div</code>	RW	0x3	Divisor for serial clock. <code>div_width</code> bits wide.
[31:12]	Reserved			

Table 80: Serial Clock Divisor Register

16.5 Serial Clock Mode Register (`sckmode`)

The `sckmode` register defines the serial clock polarity and phase. Table 82 and Table 83 describe the behavior of the `pol` and `pha` fields, respectively. The reset value of `sckmode` is 0.

Serial Clock Mode Register (<code>sckmode</code>)				
Register Offset		0x4		
Bits	Field Name	Attr.	Rst.	Description
0	<code>pha</code>	RW	0x0	Serial clock phase
1	<code>pol</code>	RW	0x0	Serial clock polarity
[31:2]	Reserved			

Table 81: Serial Clock Mode Register

Value	Description
0	Inactive state of SCK is logical 0
1	Inactive state of SCK is logical 1

Table 82: Serial Clock Polarity

Value	Description
0	Data is sampled on the leading edge of SCK and shifted on the trailing edge of SCK
1	Data is shifted on the leading edge of SCK and sampled on the trailing edge of SCK

Table 83: Serial Clock Phase

16.6 Chip Select ID Register (`csid`)

The `csid` is a $\log_2(cs_width)$ -bit register that encodes the index of the CS pin to be toggled by hardware chip select control. The reset value is 0x0.

Chip Select ID Register (csid)				
Register Offset		0x10		
Bits	Field Name	Attr.	Rst.	Description
[31:0]	csid	RW	0x0	Chip select ID. $\log_2(cs_width)$ bits wide.

Table 84: Chip Select ID Register

16.7 Chip Select Default Register (csdef)

The csdef register is a cs_width-bit register that specifies the inactive state (polarity) of the CS pins. The reset value is high for all implemented CS pins.

Chip Select Default Register (csdef)				
Register Offset		0x14		
Bits	Field Name	Attr.	Rst.	Description
[31:0]	csdef	RW	0x1	Chip select default value. cs_width bits wide, reset to all-1s.

Table 85: Chip Select Default Register

16.8 Chip Select Mode Register (csmode)

The csmode register defines the hardware chip select behavior as described in Table 86. The reset value is 0x0 (AUTO). In HOLD mode, the CS pin is deasserted only when one of the following conditions occur:

- A different value is written to csmode or csid.
- A write to csdef changes the state of the selected pin.
- Direct-mapped flash mode is enabled.

Chip Select Mode Register (csmode)				
Register Offset		0x18		
Bits	Field Name	Attr.	Rst.	Description
[1:0]	mode	RW	0x0	Chip select mode
[31:2]	Reserved			

Table 86: Chip Select Mode Register

Value	Name	Description
0	AUTO	Assert/deassert CS at the beginning/end of each frame
2	HOLD	Keep CS continuously asserted after the initial frame
3	OFF	Disable hardware control of the CS pin

Table 87: Chip Select Modes

16.9 Delay Control Registers (`delay0` and `delay1`)

The `delay0` and `delay1` registers allow for the insertion of arbitrary delays specified in units of one SCK period.

The `cssck` field specifies the delay between the assertion of CS and the first leading edge of SCK. When `sckmode.pha = 0`, an additional half-period delay is implicit. The reset value is `0x1`.

The `sckcs` field specifies the delay between the last trailing edge of SCK and the deassertion of CS. When `sckmode.pha = 1`, an additional half-period delay is implicit. The reset value is `0x1`.

The `intercs` field specifies the minimum CS inactive time between deassertion and assertion. The reset value is `0x1`.

The `interxfr` field specifies the delay between two consecutive frames without deasserting CS. This is applicable only when `sckmode` is HOLD or OFF. The reset value is `0x0`.

Delay Control Register 0 (<code>delay0</code>)				
Register Offset		0x28		
Bits	Field Name	Attr.	Rst.	Description
[7:0]	<code>cssck</code>	RW	0x1	CS to SCK Delay
[15:8]	Reserved			
[23:16]	<code>sckcs</code>	RW	0x1	SCK to CS Delay
[31:24]	Reserved

[7:0]	<code>intercs</code>	RW	0x1	Minimum CS inactive time
[15:8]	Reserved			
[23:16]	<code>interxfr</code>	RW	0x0	Maximum interframe delay
[31:24]	Reserved			

Table 89: Delay Control Register 1

16.10 Frame Format Register (`fmt`)

The `fmt` register defines the frame format for transfers initiated through the programmed-I/O (FIFO) interface. Table 91, Table 92, and Table 93 describe the `proto`, `endian`, and `dir` fields, respectively. The `len` field defines the number of bits per frame, where the allowed range is 0 to 8 inclusive.

For flash-enabled SPI controllers, the reset value is 0x0008_0008, corresponding to proto = single, dir = Tx, endian = MSB, and len = 8. For non-flash-enabled SPI controllers, the reset value is 0x0008_0000, corresponding to proto = single, dir = Rx, endian = MSB, and len = 8.

Frame Format Register (fmt)				
Register Offset		0x40		
Bits	Field Name	Attr.	Rst.	Description
[1:0]	proto	RW	0x0	SPI protocol
2	endian	RW	0x0	SPI endianness
3	dir	RW	X	SPI I/O direction. This is reset to 1 for flash-enabled SPI controllers, 0 otherwise.
[15:4]	Reserved			
[19:16]	len	RW	0x8	Number of bits per frame
[31:20]	Reserved			

Table 90: Frame Format Register

Value	Description	Data Pins
0	Single	DQ0 (MOSI), DQ1 (MISO)
1	Dual	DQ0, DQ1
2	Quad	DQ0, DQ1, DQ2, DQ3

Table 91: SPI Protocol. Unused DQ pins are tri-stated.

Value	Description
0	Transmit most-significant bit (MSB) first
1	Transmit least-significant bit (LSB) first

Table 92: SPI Endianness

Value	Description
0	Rx: For dual and quad protocols, the DQ pins are tri-stated. For the single protocol, the DQ0 pin is driven with the transmit data as normal.
1	Tx: The receive FIFO is not populated.

Table 93: SPI I/O Direction

16.11 Transmit Data Register (txdata)

Writing to the txdata register loads the transmit FIFO with the value contained in the data field. For `fmt.len < 8`, values should be left-aligned when `fmt.endian = MSB` and right-aligned when `fmt.endian = LSB`.

The full flag indicates whether the transmit FIFO is ready to accept new entries; when set, writes to txdata are ignored. The data field returns 0x0 when read.

Transmit Data Register (txdata)				
Register Offset		0x48		
Bits	Field Name	Attr.	Rst.	Description
[7:0]	data	RW	0x0	Transmit data
[30:8]	Reserved			
31	full	RO	X	FIFO full flag

Table 94: Transmit Data Register

16.12 Receive Data Register (rxdata)

Reading the rxdata register dequeues a frame from the receive FIFO. For `fmt.len < 8`, values are left-aligned when `fmt.endian = MSB` and right-aligned when `fmt.endian = LSB`.

The empty flag indicates whether the receive FIFO contains new entries to be read; when set, the data field does not contain a valid frame. Writes to rxdata are ignored.

Receive Data Register (rxdata)				
Register Offset		0x4C		
Bits	Field Name	Attr.	Rst.	Description
[7:0]	data	RO	X	Received data
[30:8]	Reserved			
31	empty	RW	X	FIFO empty flag

Table 95: Receive Data Register

16.13 Transmit Watermark Register (txmark)

The txmark register specifies the threshold at which the Tx FIFO watermark interrupt triggers. The reset value is 1 for flash-enabled SPI controllers, and 0 for non-flash-enabled SPI controllers.

Transmit Watermark Register (txmark)				
Register Offset		0x50		
Bits	Field Name	Attr.	Rst.	Description
[2:0]	txmark	RW	X	Transmit watermark. The reset value is 1 for flash-enabled controllers, 0 otherwise.
[31:3]	Reserved			

Table 96: Transmit Watermark Register

16.14 Receive Watermark Register (rxmark)

The rxmark register specifies the threshold at which the Rx FIFO watermark interrupt triggers. The reset value is 0x0.

Receive Watermark Register (rxmark)				
Register Offset		0x54		
Bits	Field Name	Attr.	Rst.	Description
[2:0]	rxmark	RW	0x0	Receive watermark
[31:3]	Reserved			

Table 97: Receive Watermark Register

16.15 SPI Interrupt Registers (ie and ip)

The ie register controls which SPI interrupts are enabled, and ip is a read-only register indicating the pending interrupt conditions. ie is reset to zero. See Table 98.

The txwm condition becomes raised when the number of entries in the transmit FIFO is strictly less than the count specified by the txmark register. The pending bit is cleared when sufficient entries have been enqueued to exceed the watermark. See Table 99.

The rxwm condition becomes raised when the number of entries in the receive FIFO is strictly greater than the count specified by the rxmark register. The pending bit is cleared when sufficient entries have been dequeued to fall below the watermark. See Table 99.

SPI Interrupt Enable Register (ie)				
Register Offset		0x70		
Bits	Field Name	Attr.	Rst.	Description
0	txwm	RW	0x0	Transmit watermark enable
1	rxwm	RW	0x0	Receive watermark enable
[31:2]	Reserved			

Table 98: SPI Interrupt Enable Register

SPI Watermark Interrupt Pending Register (ip)				
Register Offset		0x74		
Bits	Field Name	Attr.	Rst.	Description
0	txwm	R0	0x0	Transmit watermark pending
1	rxwm	R0	0x0	Receive watermark pending
[31:2]	Reserved			

Table 99: SPI Watermark Interrupt Pending Register

16.16 SPI Flash Interface Control Register (`fctr1`)

When the `en` bit of the `fctr1` register is set, the controller enters direct memory-mapped SPI flash mode. Accesses to the direct-mapped memory region causes the controller to automatically sequence SPI flash reads in hardware. The reset value is `0x1`. See Table 100.

SPI Flash Interface Control Register (<code>fctr1</code>)				
Register Offset		0x60		
Bits	Field Name	Attr.	Rst.	Description
0	<code>en</code>	RW	0x1	SPI Flash Mode Select
[31:1]	Reserved			

Table 100: SPI Flash Interface Control Register

16.17 SPI Flash Instruction Format Register (`ffmt`)

The `ffmt` register defines the format of the SPI flash read instruction issued by the controller when the direct-mapped memory region is accessed while in SPI flash mode.

An instruction consists of a command byte followed by a variable number of address bytes, dummy cycles (padding), and data bytes. Table 101 describes the function and reset value of each field.

SPI Flash Instruction Format Register (<code>ffmt</code>)				
Register Offset		0x64		
Bits	Field Name	Attr.	Rst.	Description
0	<code>cmd_en</code>	RW	0x1	Enable sending of command
[3:1]	<code>addr_len</code>	RW	0x3	Number of address bytes (0 to 4)
[7:4]	<code>pad_cnt</code>	RW	0x0	Number of dummy cycles
[9:8]	<code>cmd_proto</code>	RW	0x0	Protocol for transmitting command
[11:10]	<code>addr_proto</code>	RW	0x0	Protocol for transmitting address and padding
[13:12]	<code>data_proto</code>	RW	0x0	Protocol for receiving data bytes
[15:14]	Reserved			
[23:16]	<code>cmd_code</code>	RW	0x3	Value of command byte
[31:24]	<code>pad_code</code>	RW	0x0	First 8 bits to transmit during dummy cycles

Table 101: SPI Flash Instruction Format Register

Chapter 17

General Purpose Input/Output Controller (GPIO)

This chapter describes the operation of the General Purpose Input/Output Controller (GPIO) on the FU540-C000. The GPIO controller is a peripheral device mapped in the internal memory map. It is responsible for low-level configuration of actual GPIO pads on the device (direction, pull up-enable, etc.), as well as selecting between various sources of the controls for these signals. The GPIO controller allows separate configuration of each of `ngpio` GPIO bits.

Atomic operations such as toggles are natively possible with the RISC-V 'A' extension.

17.1 GPIO Instance in FU540-C000

FU540-C000 contains one GPIO instance. Its address and parameters are shown in Table 102.

Instance Number	Address	ngpio
0	0x10060000	16

Table 102: GPIO Instance

17.2 Memory Map

The memory map for the GPIO control registers is shown in Table 103. The GPIO memory map has been designed to require only naturally-aligned 32-bit memory accesses. Each register is `ngpio` bits wide.

Offset	Name	Description
0x00	input_val	Pin value
0x04	input_en	Pin input enable*
0x08	output_en	Pin output enable*
0x0C	output_val	Output value
0x10	pue	Internal pull-up enable*
0x14	ds	Pin drive strength
0x18	rise_ie	Rise interrupt enable
0x1C	rise_ip	Rise interrupt pending
0x20	fall_ie	Fall interrupt enable
0x24	fall_ip	Fall interrupt pending
0x28	high_ie	High interrupt enable
0x2C	high_ip	High interrupt pending
0x30	low_ie	Low interrupt enable
0x34	low_ip	Low interrupt pending
0x40	out_xor	Output XOR (invert)

Table 103: GPIO Peripheral Register Offsets. Only naturally aligned 32-bit memory accesses are supported. Registers marked with an * are asynchronously reset to 0. All other registers are synchronously reset to 0.

17.3 Input / Output Values

The GPIO can be configured on a bitwise fashion to represent inputs and/or outputs, as set by the `input_en` and `output_en` registers. Writing to the `output_val` register updates the bits regardless of the tristate value. Reading the `output_val` register returns the written value. Reading the `input_val` register returns the actual value of the pin gated by `input_en`.

17.4 Interrupts

A single interrupt bit can be generated for each GPIO bit. The interrupt can be driven by rising or falling edges, or by level values, and interrupts can be enabled for each GPIO bit individually.

Inputs are synchronized before being sampled by the interrupt logic, so the input pulse width must be long enough to be detected by the synchronization logic.

To enable an interrupt, set the corresponding bit in the `rise_ie` and/or `fall_ie` to 1. If the corresponding bit in `rise_ip` or `fall_ip` is set, an interrupt pin is raised.

Once the interrupt is pending, it will remain set until a 1 is written to the `*_ip` register at that bit.

The interrupt pins may be routed to the PLIC or directly to local interrupts.

17.5 Internal Pull-Ups

When configured as inputs, each pin has an internal pull-up which can be enabled by software. At reset, all pins are set as inputs, and pull-ups are disabled.

17.6 Drive Strength

On the FU540-C000, the drive strength registers do not control anything about the GPIO, although the registers can be read and written.

17.7 Output Inversion

When configured as an output, the software-writable `out_xor` register is combined with the output to invert it.

Chapter 18

One-Time Programmable Memory Interface (OTP)

This chapter describes the operation of the SiFive controller for the eMemory EG004K32TQ028XW01 NeoFuse® One-Time-Programmable (OTP) memory.

18.1 OTP Overview

OTP is one-time programmable memory. Each bit starts out as 1 and can be written to 0 by using the controller interface. The OTP is laid out as a 4096×32 bit array.

The controller provides a simple register-based interface to write the inputs of the macro and read its outputs. All timing and sequencing are the responsibility of the driver software.

18.2 Memory Map

The memory map for the OTP control registers is shown in Table 104. The OTP memory map has been designed to require only naturally-aligned 32-bit memory accesses. For further information about the functionality and timing requirements of each of the inputs/outputs, refer to the datasheet for eMemory EG004K32TQ028XW01.

Offset	Name	Description
0x00	PA	Address input
0x04	PAIO	Programming address input
0x08	PAS	Program redundancy cell selection input
0x0C	PCE	OTP Macro enable input
0x10	PCLK	Clock input
0x14	PDIN	Write data input
0x18	PDOUT	Read Data output
0x1C	PDSTB	Deep standby mode enable input (active low)
0x20	PPROG	Program mode enable input
0x24	PTC	Test column enable input
0x28	PTM	Test mode enable input
0x2C	PTM_REP	Repair function test mode enable input
0x30	PTR	Test row enable input
0x34	PTRIM	Repair function enable input
0x38	PWE	Write enable input (defines program cycle)

Table 104: Register offsets within the eMemory OTP Controller memory map

18.3 Detailed Register Fields

Each register is described in more detail below.

PA: Address input (PA)				
Register Offset		0x0		
Bits	Field Name	Attr.	Rst.	Description
[11:0]	PA	RW	0x0	Address input
[31:12]	Reserved

[31:1]	Reserved			

Table 118: PTRIM: Repair function enable input

PWE: Write enable input (defines program cycle) (PWE)				
Register Offset		0x38		
Bits	Field Name	Attr.	Rst.	Description
0	PWE	RW	0x0	Write enable input (defines program cycle)
[31:1]	Reserved			

Table 119: PWE: Write enable input (defines program cycle)

18.4 OTP Contents in the FU540-C000

SiFive reserves the first 1 KiB of the 16 KiB OTP memory for internal use.

The current usage is shown in Table 120, with an example where the stored serial number is 0x00000001:

32-bit Offset	serial	serial_n
0xFC	0x1	0xffffffe
0xFE	0xffffffff	0xffffffff

Table 120: Initial OTP Contents for example Serial Number 0x1

The serial number stored in OTP can be found using this method:

```
for (i = 0xfe; i > 0; i -= 2)
    serial = read_otp_word(i);
    serial_n = read_otp_word(i+);
    if (serial == ~serial_n)
        break;
```

Chapter 19

Gigabit Ethernet Subsystem

This chapter describes the operation of Gigabit Ethernet on the FU540-C000.

19.1 Gigabit Ethernet Overview

FU540-C000 integrates a single Cadence GEMGX^L Gigabit Ethernet Controller that implements full-duplex 10/100/1000 Mb/s Ethernet MAC as defined in IEEE Standard for Ethernet (IEEE Std. 802.3-2008). The Gigabit Ethernet controller interfaces to an external PHY using Gigabit Media Independent Interface (GMII).

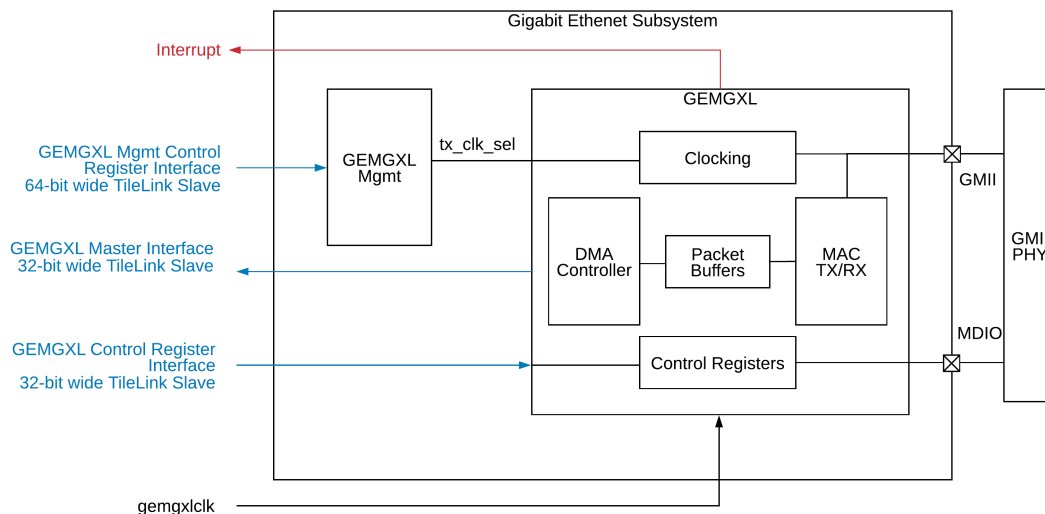

Figure 9: Gigabit Ethernet Subsystem architecture.

The GEMGX^L is parameterized to support the following features:

- IEEE Standard 802.3-2008 supporting 10/100/1000 Mbps operation
- GMII/MII interface

- MDIO interface for physical layer management of external PHY
- Flow Control. Full duplex mode and half duplex operation with TX/RX of pause frames
- Receive Traffic Policing. Ability to drop frames
- Scatter-gather 32-bit wide bus mastering DMA and 64-bit addresses
- 128-bit wide 4 KiB deep DMA RX/TX packet buffers with cut-through operation mode
- Interrupt generation to signal TX/RX completion, errors and wake-up
- IPv4 and IPv6 checksum offload
- Automatic pad and cyclic redundancy check (CRC) generation on transmit frames
- Jumbo frames up to 10240 bytes
- 128-bit wide 4 KiB deep RX/TX packet buffers
- 4 source/destination frame filters for use in Wake on LAN and Pause Frame Handling
- Ethernet loopback mode
- IEEE 1588 standard for precision clock synchronization protocol is not supported

The GEMGXL Management block enables software to switch the clock used for transmit logic for 10/100 mode (MII) versus gigabit (GMII) mode. In 10/100 MII mode, transmit logic in the GEMGXL must be clocked from a free-running clock (TX_CLK) generated by the external PHY. In gigabit GMII mode, the GEMGXL, not the external PHY, must generate the 125 MHz transmit clock towards the PHY.

The Gigabit Ethernet Subsystem operates on a separate clock.

19.2 Memory Map

This section presents an overview of the GEMGXL control registers.

19.2.1 GEMGXL Management Block Control Registers (0x100A_0000–0x100A_FFFF)

GEMGXL Management TX Clock Select Register			
Base Address		0x100A_0000	
Bits	Field Name	Rst.	Description
0	tx_clk_sel	0x0	GEMGXL TX clock operation mode: 0 = GMII mode. Use 125 MHz gemgx1clk from PRCI in TX logic and output clock on GMII output signal GTX_CLK 1 = MII mode. Use MII input signal TX_CLK in TX logic

Table 121: GEMGXL Management TX Clock Select Register

GEMGXL Management Control Status Speed Mode Register			
Base Address		0x100A_0020	
Bits	Field Name	Rst.	Description
[3:0]	control_status_speed_mode	0x0	4' b0000 = 10 Mbps Ethernet operation using MII interface 4' b0001 = 100 Mbps Ethernet operation using MII interface 4' b001x = 1000 Mbps Ethernet operation using GMII interface

Table 122: GEMGXL Management Control Status Speed Mode Register

19.2.2 GEMGXL Control Registers (0x1009_0000–0x1009_1FFF)

The complete memory map of the GEMGXL device is described in the Cadence GEMGXL macb Linux driver header:

<https://github.com/torvalds/linux/blob/v4.15/drivers/net/ethernet/cadence/macb.h>

19.3 Initialization and Software Interface

Clocking and reset is initialized in the First Stage Boot Loader (FSBL) as described in Chapter 7.

The Gigabit Ethernet Subsystem is controlled by the Cadence GEMGXL macb Linux driver:

https://github.com/torvalds/linux/blob/v4.15/drivers/net/ethernet/cadence/macb_main.c

The switching of GEMGXL TXCLK by the GEMGXL Management Block is controlled by a second Linux driver:

<https://github.com/riscv/riscv-linux/blob/riscv-linux-4.15/drivers/clk/sifive/gemgxl-mgmt.c>

Chapter 20

DDR Subsystem

This chapter describes the operation of the DDR subsystem on the FU540-C000.

20.1 DDR Subsystem Overview

The DDR subsystem supports external 32/64-bit wide DDR3, DDR3L, or DDR4 DRAM with optional ECC. The maximum data rate is 2400 MT/s. The maximum memory depth is 128 GiB implemented as 1 or 2 ranks.

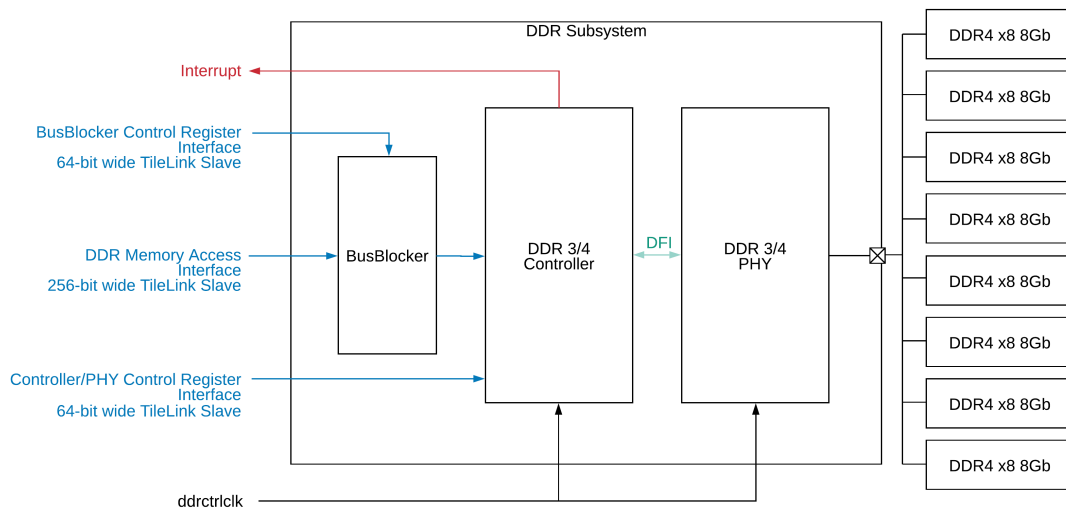

Figure 10: DDR Subsystem architecture

The DDR Subsystem consists of three main blocks:

1. DDR PHY. Analog PADs. Digital high-speed training and alignment circuits.
2. DDR Controller. Generation of DDR Read/Write/Refresh commands to PHY DFI interface.

3. Bus Blocker. Prevents memory accesses to the DDR controller that are within the maximum DDR 128 GiB range but beyond the range of the attached DRAM devices.

The DDR Subsystem operates on a separate clock, `ddrctrlclk`, running at 1/4 DDR data rate with clock domain crossers to the TileLink clock TLCLK.

There are three TileLink slave interfaces:

1. DDR Memory Access Interface. A 256-bit wide TileLink slave node.
2. Bus Blocker Control Register Interface. A 64-bit wide TileLink slave node.
3. DDR Controller/Phy Control Register Interface A 64-bit wide TileLink slave node.

A single interrupt output is connected to the PLIC.

20.2 Memory Map

20.2.1 Bus Blocker Control Registers (0x100B_8000–0x100B_8FFF)

The Bus Blocker contains a single control register that enables/disables it and defines the upper address of attached DDR.

DDR Subsystem Bus Blocker Control Register 0			
Base Address		0x100B_8000	
Bits	Field Name	Rst.	Description
[53:0]	address [55:2]	0x0	Upper DDR address bits [55:2]
[59:56]	enable_disable	0x0	0xF to enable Bus Blocker. This register can only be toggled once after reset.

Table 123: DDR Subsystem Bus Blocker Control Register 0

20.2.2 DDR Controller and PHY Control Registers (0x100B_0000–0x100B_3FFF)

16 KiB of memory-mapped registers control the DDR controller and the PHY mode of operation. For example, memory timing settings, PAD mode configuration, initialization, and training.

The First Stage Boot Loader (FSBL) directly computes the contents of a subset of these registers as part of the DDR Reset and Initialization process. These registers are documented below. Please contact SiFive directly to determine the complete register settings for your application.

DDR Controller Control Register 0			
Base Address		0x100B_0000	
Bits	Field Name	Rst.	Description
0	start	0x0	Start initialization of DDR Subsystem
[11:8]	dram_class	0x0	DDR3:0x6 DDR4:0xA

Table 124: DDR Controller Control Register 0

DDR Controller Control Register 19			
Base Address		0x100B_004C	
Bits	Field Name	Rst.	Description
[18:16]	bstlen	0x2	Encoded burst length. BL1=0x1 BL2=0x2 BL4=0x3 BL8=3

Table 125: DDR Controller Control Register 19

DDR Controller Control Register 21			
Base Address		0x100B_0054	
Bits	Field Name	Rst.	Description
0	optimal_rmodew_en	0	Enables DDR controller optimized Read Modify Write logic

Table 126: DDR Controller Control Register 21

DDR Controller Control Register 120			
Base Address		0x100B_01E0	
Bits	Field Name	Rst.	Description
16	diable_rd_interleave	0	Disable read data interleaving. Set to 1 in FSBL for valid TileLink operation

Table 127: DDR Controller Control Register 120

DDR Controller Control Register 132			
Base Address		0x100B_0210	
Bits	Field Name	Rst.	Description
7	int_status[7]	0	An error has occurred on the port command channel
8	int_status[8]	0	The memory initialization has been completed

Table 128: DDR Controller Control Register 132

DDR Controller Control Register 136			
Base Address		0x100B_0220	
Bits	Field Name	Rst.	Description
[31:0]	int_mask	0	MASK interrupt due to cause INT_STATUS [31:0]

Table 129: DDR Controller Control Register 136

20.2.3 DDR Memory (0x8000_0000–0x1F_7FFF_FFFF)

The attached DDR is memory mapped starting at address 0x8000_0000.

20.3 Reset and Initialization

At power-on, the DDR Subsystem is held in reset by the PRCI block.

The DDR Subsystem is initialized in the First Stage Boot Loader (FSBL) as follows:

1. The DDR Subsystem DDRCTRLCLK input clock is started. DDRPLL in the PRCI is programmed to generate the DDR Subsystem clock, which runs at 1/4 the memory MT/s. See Chapter 7.
2. The DDR Subsystem is brought out of reset.
 - a. The DDR controller reset is released by setting the PRCI Peripheral Devices Reset Control Register (devicesresetreg) field ddr_ctrl_rst_n to 1.
 - b. A wait of one full DDRCTRLCLK cycles occurs.
 - c. The DDR controller register interface reset and DDR Subsystem PHY reset are released by setting PRCI register fields ddr_axi_rst_n, ddr_ahb_rst_n and ddr_phy_rst_n to 1.
 - d. A wait of 256 full DDRCTRLCLK cycles occurs.
3. The DDR Controller configuration registers at address 0x100B_0000 to 0x100B_0424 are set. The start register field in the DDR Subsystem Control Register 0 (0x100B_0000) is held at 0.
4. The DDR PHY configuration registers from address 0x100B_5200 to 0x100B_52F8 are set.
5. The DDR PHY configuration registers from address 0x100B_4000 to 0x100B_51FC are set.
6. The "encoded burst length" bst1en field in DDR Subsystem Control Register 19 is set at address 0x100B_004C.
7. All interrupts are disabled by setting int_mask in DDR Subsystem control register 136 at address 0x100B_0220 to 0xFFFF_FFFF.

8. The `start` register field in DDR Subsystem Control Register 0 at address `0x100B_0000` is set to 1, activating the DDR calibration and training operation.
9. The CPU waits for memory initialization completion, polling register `int_status[8]` in DDR Subsystem Control Register 132 (`0x100B_0210`).
10. The Bus Blocker in front of the DDR controller memory slave port is disabled by setting Bus Blocker Control Register 0 at address `0x100B_8000`. Bits 56 to 59 are set to 0xF enabling all memory operations. The least significant bits are set to the upper DDR address in 32-bit words.
11. The DDR Subsystem is ready to service memory accesses at base address `0x8000_0000`.

Chapter 21

Error Device

The error device is a TileLink slave that responds to all requests with a TileLink error. It has no registers. The entire memory range discards writes and returns zeros on read. Both operation acknowledgments carry an error indication.

The error device serves a dual role. Internally, it is used as a landing pad for illegal off-chip requests. However, it also useful for testing software handling of bus errors.

Chapter 22

ChipLink

ChipLink is an off-chip serialization of the TileLink protocol, used to connect to an optional expansion board. In the FU540-C000, it is implemented as a source-synchronous single-data-rate parallel bus. Source code implementing this prototype protocol can be found in the SiFive-Blocks GitHub repository.

ChipLink supports:

- off-chip cache-coherent bus masters (e.g., in an FPGA)
- off-chip memory-mapped slave devices
- credit-based flow control to absorb off-chip latency
- out-of-order completion to unblock concurrent operations
- optional in-order completion to speed up serial masters

Several address ranges in the FU540-C000 point at ChipLink. Address ranges below 2 GiB are used for 32-bit-only devices, whereas the large address ranges above 2 GiB make it possible to memory map large devices or memories. One pair of ranges is marked uncacheable address space, which can be used for MMIO devices. Another pair of ranges are behind the L2 cache, suitable for attaching large memory devices. See Table 130.

Note

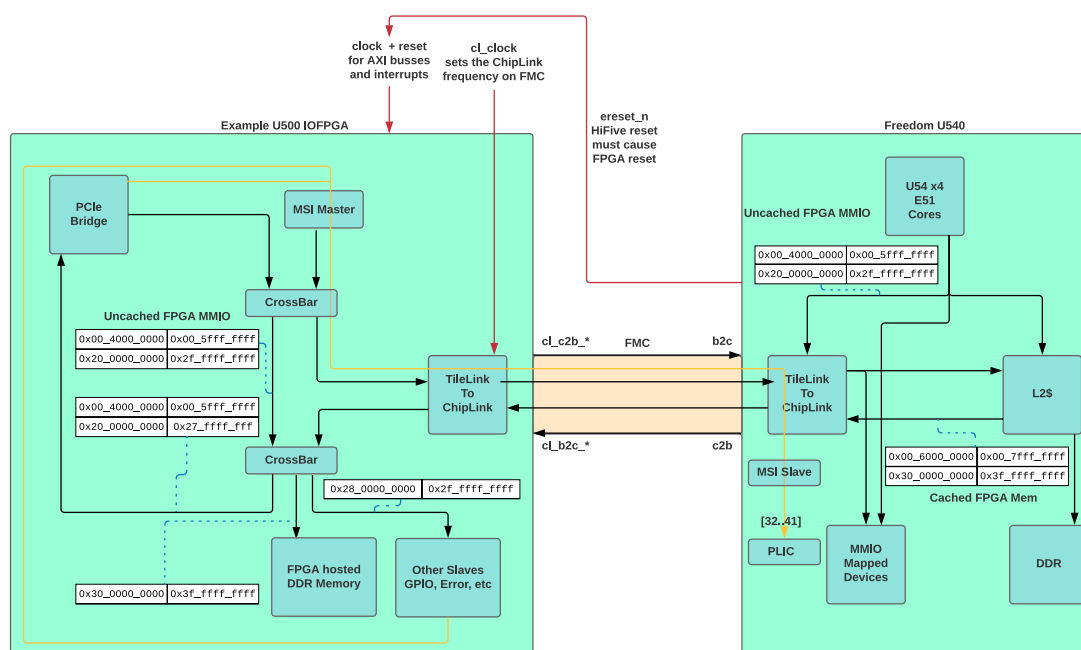

If an off-chip master wishes to access memory that is cached by the L2, it must access that memory through the FU540-C000 via ChipLink. The request may be serviced by the L2 or the L2 may in turn request the memory from an off-chip slave. Attempting to access the memory directly off-chip will result in data corruption.

Address	Size	Use	Note
0x00_4000_0000	0x00_2000_0000	MMIO	Uncached
0x00_6000_0000	0x00_2000_0000	Memory	Cached by L2
0x20_0000_0000	0x10_0000_0000	MMIO	Uncached
0x30_0000_0000	0x10_0000_0000	Memory	Cached by L2

Table 130: ChipLink Memory Map

An example FPGA design suitable for use bridging PCI Express (PCIe) to the FU540-C000 can be found in the SiFive-Blocks GitHub repository. In the block diagram below, the example iofpga design is illustrated. Additional cache-coherent TL-C or TL-UH masters can be connected to the upper crossbar while additional MMIO slaves can be connected to the lower crossbar.

FREEDOM U540 CHIPLINK ADDRESSING

22.1 Message Signaled Interrupts (MSI)

To transport interrupts from off-chip to the FU540-C000, the FU540-C000 includes a MSI Slave device. This device simply connects bus-mapped one-bit registers with 32-bit spacing to interrupts connected to the PLIC. On the far side of ChipLink, there is a MSI Master that translates edges on incoming interrupt lines into writes to these registers on the MSI Slave.

This mechanism makes it possible for devices in the FPGA to connect their interrupts to the PLIC via this ChipLink bus. Beyond a ~100 ns increased interrupt latency, this interrupt forwarding is completely invisible to devices in the FPGA.

Chapter 23

Debug

This chapter describes the operation of SiFive debug hardware, which follows *The RISC-V Debug Specification 0.13*. Currently only interactive debug and hardware breakpoints are supported.

23.1 Debug CSRs

This section describes the per-hart trace and debug registers (TDRs), which are mapped into the CSR space as follows:

CSR Name	Description	Allowed Access Modes
tselect	Trace and debug register select	D, M
tdata1	First field of selected TDR	D, M
tdata2	Second field of selected TDR	D, M
tdata3	Third field of selected TDR	D, M
dcsr	Debug control and status register	D
dpc	Debug PC	D
dscratch	Debug scratch register	D

Table 131: Debug Control and Status Registers

The dcsr, dpc, and dscratch registers are only accessible in debug mode, while the tselect and tdata1-3 registers are accessible from either debug mode or machine mode.

23.1.1 Trace and Debug Register Select (tselect)

To support a large and variable number of TDRs for tracing and breakpoints, they are accessed through one level of indirection where the tselect register selects which bank of three tdata1-3 registers are accessed via the other three addresses.

The tselect register has the format shown below:

Trace and Debug Select Register			
CSR	tselect		
Bits	Field Name	Attr.	Description
[31:0]	index	WARL	Selection index of trace and debug registers

Table 132: tselect CSR

The index field is a **WARL** field that does not hold indices of unimplemented TDRs. Even if index can hold a TDR index, it does not guarantee the TDR exists. The type field of tdata1 must be inspected to determine whether the TDR exists.

23.1.2 Trace and Debug Data Registers (tdata1-3)

The tdata1-3 registers are XLEN-bit read/write registers selected from a larger underlying bank of TDR registers by the tselect register.

Trace and Debug Data Register 1			
CSR	tdata1		
Bits	Field Name	Attr.	Description
[27:0]	TDR-Specific Data		
[31:28]	type	RO	Type of the trace & debug register selected by tselect

Table 133: tdata1 CSR

Trace and Debug Data Registers 2 and 3			
CSR	tdata2/3		
Bits	Field Name	Attr.	Description
[31:0]	TDR-Specific Data		

Table 134: tdata2/3 CSRs

The high nibble of tdata1 contains a 4-bit type code that is used to identify the type of TDR selected by tselect. The currently defined types are shown below:

Type	Description
0	No such TDR register
1	Reserved
2	Address/Data Match Trigger
≥ 3	Reserved

Table 135: tdata Types

The dmode bit selects between debug mode (dmode=1) and machine mode (dmode=0) views of the registers, where only debug mode code can access the debug mode view of the TDRs. Any

attempt to read/write the `tdata1-3` registers in machine mode when `dmode=1` raises an illegal instruction exception.

23.1.3 Debug Control and Status Register (`dcsr`)

This register gives information about debug capabilities and status. Its detailed functionality is described in *The RISC-V Debug Specification 0.13*.

23.1.4 Debug PC `dpc`

When entering debug mode, the current PC is copied here. When leaving debug mode, execution resumes at this PC.

23.1.5 Debug Scratch `dscratch`

This register is generally reserved for use by Debug ROM in order to save registers needed by the code in Debug ROM. The debugger may use it as described in *The RISC-V Debug Specification 0.13*.

23.2 Breakpoints

The FU540-C000 supports two hardware breakpoint registers per hart, which can be flexibly shared between debug mode and machine mode.

When a breakpoint register is selected with `tselect`, the other CSRs access the following information for the selected breakpoint:

CSR Name	Breakpoint Alias	Description
<code>tselect</code>	<code>tselect</code>	Breakpoint selection index
<code>tdata1</code>	<code>mcontrol</code>	Breakpoint match control
<code>tdata2</code>	<code>maddress</code>	Breakpoint match address
<code>tdata3</code>	N/A	Reserved

Table 136: TDR CSRs when used as Breakpoints

23.2.1 Breakpoint Match Control Register `mcontrol`

Each breakpoint control register is a read/write register laid out in Table 137.

Breakpoint Control Register (mcontrol1)				
Register Offset		CSR		
Bits	Field Name	Attr.	Rst.	Description
0	R	WARL	X	Address match on LOAD
1	W	WARL	X	Address match on STORE
2	X	WARL	X	Address match on Instruction FETCH
3	U	WARL	X	Address match on User Mode
4	S	WARL	X	Address match on Supervisor Mode
5	Reserved	WPRI	X	Reserved
6	M	WARL	X	Address match on Machine Mode
[10:7]	match	WARL	X	Breakpoint Address Match type
11	chain	WARL	0	Chain adjacent conditions.
[17:12]	action	WARL	0	Breakpoint action to take. 0 or 1.
18	timing	WARL	0	Timing of the breakpoint. Always 0.
19	select	WARL	0	Perform match on address or data. Always 0.
20	Reserved	WPRI	X	Reserved
[26:21]	maskmax	RO	4	Largest supported NAPOT range
27	dmode	RW	0	Debug-Only access mode
[31:28]	type	RO	2	Address/Data match type, always 2

Table 137: Test and Debug Data Register 3

The type field is a 4-bit read-only field holding the value 2 to indicate this is a breakpoint containing address match logic.

The bpaction field is an 8-bit read-write **WARL** field that specifies the available actions when the address match is successful. The value 0 generates a breakpoint exception. The value 1 enters debug mode. Other actions are not implemented.

The R/W/X bits are individual **WARL** fields, and if set, indicate an address match should only be successful for loads/stores/instruction fetches, respectively, and all combinations of implemented bits must be supported.

The M/S/U bits are individual **WARL** fields, and if set, indicate that an address match should only be successful in the machine/supervisor/user modes, respectively, and all combinations of implemented bits must be supported.

The match field is a 4-bit read-write **WARL** field that encodes the type of address range for breakpoint address matching. Three different match settings are currently supported: exact, NAPOT, and arbitrary range. A single breakpoint register supports both exact address matches and matches with address ranges that are naturally aligned powers-of-two (NAPOT) in size. Breakpoint registers can be paired to specify arbitrary exact ranges, with the lower-numbered breakpoint register giving the byte address at the bottom of the range and the higher-numbered

breakpoint register giving the address 1 byte above the breakpoint range, and using the `chain` bit to indicate both must match for the action to be taken.

NAPOT ranges make use of low-order bits of the associated breakpoint address register to encode the size of the range as follows:

maddress	Match type and size
a...aaaaaa	Exact 1 byte
a...aaaaa0	2-byte NAPOT range
a...aaaa01	4-byte NAPOT range
a...aaa011	8-byte NAPOT range
a...aa0111	16-byte NAPOT range
a...a01111	32-byte NAPOT range
...	...
a01...1111	2^{31} -byte NAPOT range

Table 138: NAPOT Size Encoding

The `maskmax` field is a 6-bit read-only field that specifies the largest supported NAPOT range. The value is the logarithm base 2 of the number of bytes in the largest supported NAPOT range. A value of 0 indicates that only exact address matches are supported (1-byte range). A value of 31 corresponds to the maximum NAPOT range, which is 2^{31} bytes in size. The largest range is encoded in `maddress` with the 30 least-significant bits set to 1, bit 30 set to 0, and bit 31 holding the only address bit considered in the address comparison.

To provide breakpoints on an exact range, two neighboring breakpoints can be combined with the `chain` bit. The first breakpoint can be set to match on an address using action of 2 (greater than or equal). The second breakpoint can be set to match on address using action of 3 (less than). Setting the `chain` bit on the first breakpoint prevents the second breakpoint from firing unless they both match.

23.2.2 Breakpoint Match Address Register (`maddress`)

Each breakpoint match address register is an `XLEN`-bit read/write register used to hold significant address bits for address matching and also the unary-encoded address masking information for NAPOT ranges.

23.2.3 Breakpoint Execution

Breakpoint traps are taken precisely. Implementations that emulate misaligned accesses in software will generate a breakpoint trap when either half of the emulated access falls within the address range. Implementations that support misaligned accesses in hardware must trap if any byte of an access falls within the matching range.

Debug-mode breakpoint traps jump to the debug trap vector without altering machine-mode registers.

Machine-mode breakpoint traps jump to the exception vector with "Breakpoint" set in the `mcause` register and with `badaddr` holding the instruction or data address that caused the trap.

23.2.4 Sharing Breakpoints Between Debug and Machine Mode

When debug mode uses a breakpoint register, it is no longer visible to machine mode (that is, the `tdrtype` will be 0). Typically, a debugger will leave the breakpoints alone until it needs them, either because a user explicitly requested one or because the user is debugging code in ROM.

23.3 Debug Memory Map

This section describes the debug module's memory map when accessed via the regular system interconnect. The debug module is only accessible to debug code running in debug mode on a hart (or via a debug transport module).

23.3.1 Debug RAM and Program Buffer (0x300–0x3FF)

The FU540-C000 has 16 32-bit words of program buffer for the debugger to direct a hart to execute arbitrary RISC-V code. Its location in memory can be determined by executing `aiupc` instructions and storing the result into the program buffer.

The FU540-C000 has two 32-bit words of debug data RAM. Its location can be determined by reading the `DMHARTINFO` register as described in the RISC-V Debug Specification. This RAM space is used to pass data for the Access Register abstract command described in the RISC-V Debug Specification. The FU540-C000 supports only general-purpose register access when harts are halted. All other commands must be implemented by executing from the debug program buffer.

In the FU540-C000, both the program buffer and debug data RAM are general-purpose RAM and are mapped contiguously in the Core Complex memory space. Therefore, additional data can be passed in the program buffer, and additional instructions can be stored in the debug data RAM.

Debuggers must not execute program buffer programs that access any debug module memory except defined program buffer and debug data addresses.

The FU540-C000 does not implement the `DMSTATUS.anyhavereset` or `DMSTATUS.allhavereset` bits.

23.3.2 Debug ROM (0x800–0xFFF)

This ROM region holds the debug routines on SiFive systems. The actual total size may vary between implementations.

23.3.3 Debug Flags (0x100–0x110, 0x400–0x7FF)

The flag registers in the debug module are used for the debug module to communicate with each hart. These flags are set and read used by the debug ROM and should not be accessed by any program buffer code. The specific behavior of the flags is not further documented here.

23.3.4 Safe Zero Address

In the FU540-C000, the debug module contains the address 0x0 in the memory map. Reads to this address always return 0, and writes to this address have no impact. This property allows a "safe" location for unprogrammed parts, as the default mtvec location is 0x0.

Chapter 24

Debug Interface

The SiFive FU540-C000 includes the JTAG debug transport module (DTM) described in *The RISC-V Debug Specification 0.13*. This enables a single external industry-standard 1149.1 JTAG interface to test and debug the system. The JTAG interface is directly connected to input pins.

24.1 JTAG TAPC State Machine

The JTAG controller includes the standard TAPC state machine shown in Figure 11. The state machine is clocked with TCK. All transitions are labelled with the value on TMS, except for the arc showing asynchronous reset when TRST=0.

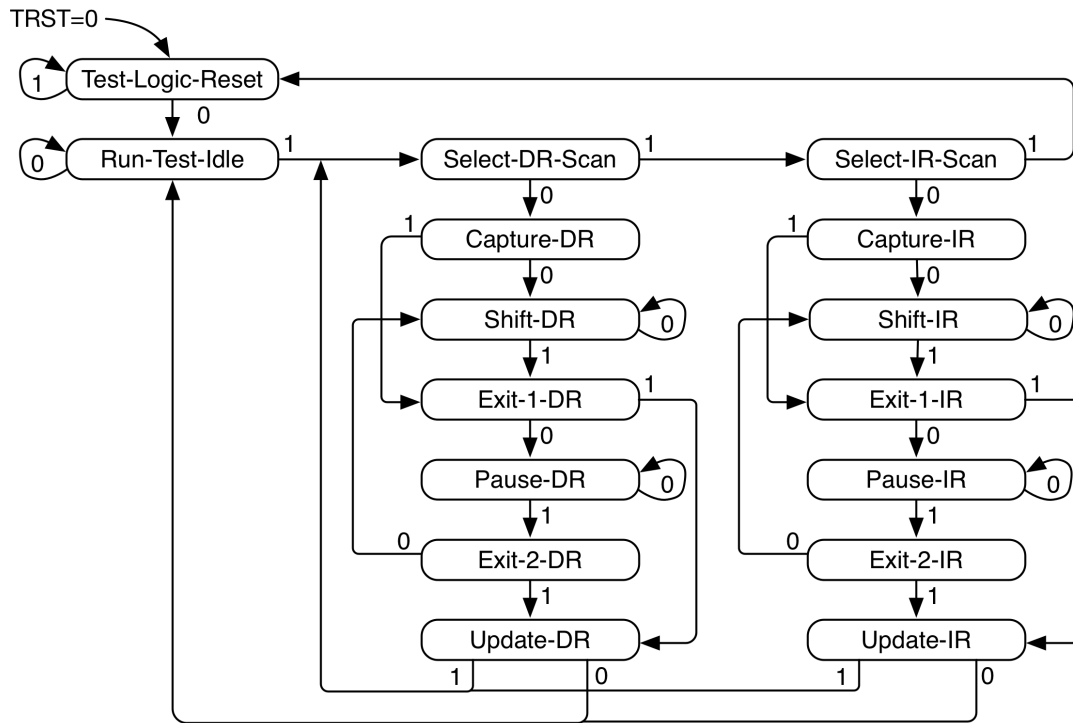

Figure 11: JTAG TAPC state machine.

24.2 Resetting JTAG Logic

The JTAG logic must be asynchronously reset by asserting the power-on-reset signal. This drives an internal `jtag_reset` signal.

Asserting `jtag_reset` resets both the JTAG DTM and debug module test logic. Because parts of the debug logic require synchronous reset, the `jtag_reset` signal is synchronized inside the FU540-C000.

During operation, the JTAG DTM logic can also be reset without `jtag_reset` by issuing 5 `jtag_TCK` clock ticks with `jtag_TMS` asserted. This action resets only the JTAG DTM, not the debug module.

24.3 JTAG Clocking

The JTAG logic always operates in its own clock domain clocked by `jtag_TCK`. The JTAG logic is fully static and has no minimum clock frequency. The maximum `jtag_TCK` frequency is part-specific.

24.4 JTAG Standard Instructions

The JTAG DTM implements the BYPASS and IDCODE instructions.

On the FU540-C000, the IDCODE is set to 0x20000913.

24.5 JTAG Debug Commands

The JTAG DEBUG instruction gives access to the SiFive debug module by connecting the debug scan register between `jtag_TDI` and `jtag_TDO`.

The debug scan register includes a 2-bit opcode field, a 7-bit debug module address field, and a 32-bit data field to allow various memory-mapped read/write operations to be specified with a single scan of the debug scan register.

These are described in *The RISC-V Debug Specification 0.13*.

Chapter 25

Errata

This section lists all known issues found in FU540-C000.

25.1 ROCK-1: ITIM de-allocation corrupts I-cache contents

Problem

When decreasing the amount of L1 I-cache memory mapped to the ITIM, instructions stored in the I-cache can become corrupted.

Implication

Programs run on a core after ITIM memory has been decreased may exhibit unpredictable behavior.

Workaround

ITIM de-allocation can only be performed by the core that owns the ITIM using the following instruction sequence:

```
.align 3
sb x0, (t0)
fence.i
```

25.2 ROCK-2: High 24 address bits are ignored

Problem

When accessing memory, the high 24-bits of virtual and physical addresses are sometimes unchecked. This affects indirect jumps, returns, loads, stores, and atomics.

Implication

Software that should trap with an illegal memory access sometimes continues to run.

Workaround

Do not access out-of-bound addresses in software.

25.3 ROCK-3: E51 atomic operations not ordered correctly

Problem

Acquire/release ordering semantics on atomic operations in the E51 core do not work correctly.

Implication

Loads and stores may appear to be re-ordered relative to atomic operations in a way that is illegal under the RISC-V memory model.

Workaround

Set both acquire and release bits on atomics run on the E51 core; e.g., use `amoor.d.aqr1` instead of `amoor.d.aq` or `amoor.d.rl`.

25.4 ROCK-4: The DPC CSR is not sign-extended

Problem

The DPC CSR correctly retains only the low 40 bits of the PC when entering debug mode. When the CSR is read, the result should be sign-extended to 64 bits but is not.

Implication

The debugger reports the PC with the high 24 bits always zero. This does not affect return from debug mode (because the PC is also only 40 bits).

Workaround

The debugger can sign-extend DPC itself.

25.5 ROCK-5: Watchpoints fire after stores are issued

Problem

The RISC-V debug specification allows implementations to either break on the store instruction before it has been executed or to break on the instruction following a store after it has been executed. Cores with this errata break on the store, after it has been executed and self-report to the debugger that they do not execute watch-pointed stores, i.e., that timing is before.

Implication

Watchpoints on memory with side effects will cause that side effect to occur twice. For example, if a watchpoint is set on the UART TX register, a write to the UART TX register will cause a character to be transmitted and the watchpoint to fire. Once the program is resumed, that same character will be transmitted again. The same double-write will occur with watch-points on memory-backed addresses, but the second write typically has no visible effect.

Workaround

Do not put watchpoints on memory with side effects. Do not expect to see the old value in memory after a watchpoint has fired.

25.6 CCACHE-1: L2 ECC failed address reporting flawed

Problem

Under memory contention, an uncorrectable ECC failure in the L2 will sometimes report the wrong address in the registers `DatECCFailHigh` and `DatECCFailLow`.

Implication

It is impossible to be certain what memory was corrupted when an uncorrectable L2 ECC failure occurs.

Workaround

Treat all L2 ECC uncorrectable failures as fatal.

25.7 I2C-1: I2C interrupt can not be cleared

Problem

The I2C controller command `IACK` (interrupt acknowledge) does not work.

Implication

The I2C controller's interrupt can not be lowered, rendering it unusable.

Workaround

Poll the I2C controller state to wait for `TIP` (transaction in progress) to go low.
